13. ABSTRACT (Maximum 200 words)  A 1:20-scale experimental model investigation was conducted to investigate the wave transmission response of a breakwater proposed for Olcott Harbor, New York. A check of the structure's stability showed the proposed section to be conservatively stable. Therefore, an alternate plan also was investigated in an attempt to reduce construction costs for the breakwater. Based on model tests results, it was concluded that: a. Both plans tested are stable designs for the maximum wave heights that can be expected to occur (6- to 10-sec waves at still-water levels of +4.3 and +5.1 ft low-water datum). b. Maximum transmitted wave heights were 0.9 and 1.5 ft for Plans 1 and 1A, respectively.

# Preface

---

The model investigation described herein was requested by the US Army Engineer District, Buffalo (NCB), in a letter to the US Army Engineer Waterways Experiment Station (WES) dated 5 June 1990. Funding authorization was granted by NCB in Intra-Army Order No. NCB-IA-90-27EJ, dated 5 June 1990.

The study was conducted by personnel of the Coastal Engineering Research Center (CERC), WES, under the general direction of Dr. James R. Houston, Chief, CERC, and Mr. Charles C. Calhoun, Jr., Assistant Chief, CERC. Direct guidance was provided by Messrs. C. E. Chatham, Chief, Wave Dynamics Division (WDD), and D. Donald Davidson, Chief, Wave Research Branch (WRB), WDD. Tests were conducted by Ms. Brenda J. Wright and Messrs. Willie G. Dubose and C. Ray Herrington, Engineering Technicians, under the direction of Mr. Robert D. Carver, Principal Investigator. This report was prepared by Mr. Carver.

COL Larry B. Fulton, EN, was the Commander and Director of WES during report publication. Dr. Robert W. Whalin was Technical Director.

# Conversion Factors, Non-SI to SI Units of Measurement

---

Non-SI units of measurement used in this report can be converted to SI units as follows:

Multiply	By	To Obtain
cubic feet	0.02831685	cubic metres
degrees (angle)	0.01745329	radians
feet	0.3048	metres
pounds (mass)	0.4535924	kilograms
pounds (mass) per cubic foot	16.01846	kilograms per cubic metre
square feet	0.09290304	square metres
tons (2,000 pounds, mass)	907.1847	kilograms

# 1 Introduction

---

## Prototype

Olcott Harbor, New York, is situated at the mouth of Eighteen Mile Creek on the southern shore of Lake Ontario (Figures 1 and 2). Construction of an 850-ft<sup>1</sup>-long east pier and an 873-ft-long west pier was completed in 1918. The piers were originally of stone-filled timber crib construction with timber decks. In 1930, both piers were capped with stone and concrete. Repairs were made to the east pier in 1949 by driving rows of sheetpiling on each side of the pier, filling the voids with granular fill, and capping the structure with concrete. A similar repair procedure was performed on the west pier in 1963.

Presently, the entrance channel to the harbor area inside the mouth of the creek is safe only during calm weather. Proposed channel improvements will provide an urgently needed all weather entrance channel and additional berthing area for local craft. A feasibility study was prepared by the US Army Engineer District, Buffalo (NCB), and recommended construction of breakwater, jetty, and channel improvements.

Bottin and Acuff<sup>2</sup> conducted a three-dimensional physical model study to develop the optimum plan for harbor improvements to meet small boat harbor wave height criteria. Improvements were designed to protect against waves entering through the new proposed harbor entrance and from waves overtopping the breakwater sections.

---

<sup>1</sup> A table of factors for converting non-SI units of measurement to SI units is presented on page vii.

Figure 2. Aerial view of harbor

## Purpose of Model Investigation

The initial objective of this study was to investigate the wave transmission response of the proposed breakwater. A secondary benefit of tests conducted herein, a check of the structure's stability, showed the proposed section to be conservatively stable. Therefore, an alternate plan also was investigated in an attempt to reduce construction costs for the breakwater.

## 2 The Model

---

### Model-Prototype Scale Relationships

Tests were conducted at a geometrically undistorted scale of 1:20, model to prototype. Scale selection was based on the sizes of model armor available compared with the estimated size of prototype armor required for stability, elimination of wave transmission scale effects, preclusion of stability scale effects,<sup>1</sup> and capabilities of the available wave tank. Based on Froude's model law<sup>2</sup> and the linear scale of 1:20, the following model-prototype relations were derived. Dimensions are in terms of length (L)<sup>3</sup> and time (T).

Characteristic	Dimension	Model-Prototype Scale Relation
Length	L	$L_r = 1:20$
Area	$L^2$	$A_r^2 = L_r = 1:400$
Volume	$L^3$	$V_r^3 = L_r = 1:8000$
Time	T	$T_r^{1/2} = L_r = 1:4.47$
where r = ratio of model quantities to prototype quantities A = area, ft <sup>2</sup> V = volume, ft <sup>3</sup>

<sup>2</sup> Stevens, J. C. 1942. Hydraulic Models. Manuals of Engineering Practice No. 25. New York: American Society of Civil Engineers.

<sup>3</sup> For convenience, symbols and abbreviations are listed in the Notation (Appendix A).

The specific weight of water used in model tests was assumed to be the same as the prototype and equal to 62.4 pcf. However, specific weights of model breakwater construction materials were not the same as their prototype counterparts. These variables were related using the following transference equation:

$$\frac{(W_a)_m}{(W_a)_p} = \frac{(\gamma_a)_m}{(\gamma_a)_p} \left( \frac{L_m}{L_p} \right)^3 \left[ \frac{(S_a)_p - 1}{(S_a)_m - 1} \right]^3 \quad (1)$$

where

$W_a$  = weight of individual armor unit, lb

a = armor stone

m = model quantities

p = prototype quantities

$\gamma_a$  = specific weight of armor unit, pcf

$S_a$  = specific weight of individual armor unit relative to water in which breakwater is constructed

## Test Equipment and Facilities

All tests were conducted in a concrete wave flume 3 ft wide and 150 ft long (Figure 3). A 1V-on-100H slope, representative of the existing prototype lake bottom, was molded lakeward of the test section. Irregular waves were generated by a hydraulically actuated piston-type wave machine. The test section was installed approximately 84.3 ft from the wave board.

Wave data were collected on electrical capacitance wave gages. Wave signal generation and data acquisition were controlled using a DEC Micro-Vax I computer. Wave data analyses were accomplished using a DEC VAX 3600.

## **3 Tests and Results**

---

### **Method of Constructing Test Sections**

All experimental breakwater sections were constructed to reproduce as closely as possible results of the usual methods of constructing full-scale breakwaters. The core material was dampened as it was dumped by bucket or shovel into the flume and was compacted with hand trowels to simulate natural consolidation resulting from wave action during construction of the prototype structure. Once the core material was in place, it was sprayed with a low-velocity water hose to ensure adequate compaction of the material. The underlayer stone then was added by shovel and smoothed to grade by hand or with trowels. Armor units used in the cover layers were placed in a random manner corresponding to work performed by a general coastal contractor; i.e., they were individually placed but were laid down without special orientation or fitting. After each test, the armor units were removed from the breakwater, all of the underlayer stones were replaced to the grade of the original test section, and the armor was replaced.

### **Description of Plan 1**

Plan 1 (Figure 4 and Photos 1 and 2) was constructed to a crown elevation of +14 ft low-water datum (lwd) and used armor slopes of 1V on 2H both lakeside and harbor side. A crown width of 16.2 ft, equivalent to two armor-stone diameters plus a 7-ft-wide walkway, was used. The lakeside slope was armored with two layers of 4- to 11-ton stone, whereas the harbor-side slope used only one layer of 4- to 11-ton stone. In an effort to preclude toe slippage, the first row of armor stone at the toe of each slope used the largest size stone that was available in the specified armor stone range.

Figure 4. Cross section of Plan 1

## Selection of Test Conditions

Based on siting of the breakwater in shallow water, tests were conducted with a Texel, Marsen, Arsloe (TMA) spectrum using peak wave periods ( $T_p$ ) of 6, 7, 8, 9, and 10 sec. The wave basin was calibrated for wave heights ( $H_{mo}$  values) of 3 to 12 ft measured in front of the wave generator and in front of the structure. Transmitted wave heights were measured 100 and 150 ft shoreward of the breakwater. Goda and Suzuki's<sup>1</sup> method was used to resolve the incident and reflected spectra.

## Test Results of Plan 1

Wave-attenuation test results are presented in Tables 1 and 2. Transmission coefficients ( $H_t/H_i$ ) are based on incident wave heights measured at the wave generator because these wave heights relate to the percent time of occurrence wave tables used in the harbor model.<sup>2</sup> In general, the data show that (a) there is little difference between transmitted wave heights measured at 100 to 150 ft shoreward of the structure and (b) if

<sup>1</sup> Goda, Y., and Suzuki, Y. 1976. Estimation of incident and reflected waves in random wave experiments. In *Proceedings, 15th international conference on coastal engineering*. Honolulu, Hawaii.

<sup>2</sup> Bottin and Acuff, op. cit.

the incident wave height is held constant and the wave period is increased, transmitted wave heights increase. Maximum transmitted wave heights of 0.9 ft were observed at the 9- and 10-sec wave periods.

Observations of incident wave forms, made during the wave attenuation tests, showed that the most severe wave conditions which experimentally could be made to attack the section for the selected conditions occurred at the 10-sec peak period with maximum wave height of about 11 ft. Therefore, it was decided the stability response of the proposed section could be adequately evaluated by subjecting the structure to the following storm-surge hydrograph:

Step	Swl ft, lwd	Wave Period $T_p$ , sec	Wave Height $H_{mo}$ , ft	Prototype Duration, hr
1	+4.3	10	11.1	4
2	+5.1	10	11.2	4
3	+4.3	10	11.1	4

Note: Swl = still-water level.

As evidenced in Photos 3 and 4, Plan 1 exhibited an excellent stability response. Minor rocking of a few armor stones was observed; however, none were displaced.

## Rationale and Description of Plan 1A

Based on the excellent stability response of Plan 1, it was decided to investigate alternative schemes that might reduce the structure's cost without significantly affecting its functional performance. Some of the factors that govern material volumes and costs are elevation and width of the crown, type and weight of armor, and slope on which the armor is placed. Based on discussions between NCB and US Army Engineer Waterways Experiment Station, it was decided that, in this particular study, the greatest cost savings with the least probable impact on functionality could probably be achieved by lowering the crown elevation.

Plan 1A was the same as Plan 1 except a toe elevation of -11.5 ft lwd and crown elevation of +12.5 ft lwd were used. This simulation was achieved by simply increasing the water depth 1.5 ft and assuming the new depth also represented an swl of +5.1 ft lwd. This approach reduced the freeboard by 1.5 ft and effectively achieved the same results (relative to transmission) as would have been achieved by lowering the model structure 1.5 ft.

## 4 Conclusions

---

Based on assumptions, tests, and results reported herein, it is concluded that:

- a.* Plans 1 and 1A are stable designs for the maximum wave heights that can be expected to occur (6- to 10-sec waves at swl's of +4.3 and +5.1 ft lwd.)
- b.* Maximum transmitted wave heights were 0.9 and 1.5 ft for Plans 1 and 1A, respectively.
