20. ABSTRACT (Continued).

was conducted by Raytheon Ocean Systems and the National Oceanic and Atmospheric Administration. Data were analyzed for tidal constituents by Outlaw (1983). A global grid representing Mississippi Sound and adjacent areas was constructed to interface with the GTM grid. Bottom friction mechanics were calibrated on this global grid for 20-24 September 1980 and subsequently verified for 12-16 June 1980. A hypothetical regional dredge disposal plan was considered on the global grid by increasing the size of Sand Island. A refined grid was constructed around the Pascagoula Channel in order to study alternative channel configuration effects on Mississippi Sound. Previously calibrated and verified bottom friction mechanics were further substantiated by simulating hydrodynamic conditions for the 20-24 September period over the refined grid using global grid results to supply water surface elevation boundary conditions. (The effects of doubling the width of the main Pascagoula Channel were then studied by simulating this same period with the modified channel.) Study conclusions are drawn and recommendations for additional simulation work are presented.

In addition, horizontal salinity conditions were also investigated for the 20-24 September period. Wind speed and direction were specified as meteorological inputs. A constant drag coefficient of 0.001 was employed to develop the surface wind stress, and the friction mechanism previously developed was used to implement bottom stress. Simulation results for both the Flux-Corrected Transport and the Three Time Level Explicit schemes are presented for the global grid. Effective dispersion coefficients in each coordinate direction were calibrated. The Flux-Corrected Transport global grid salinity levels and water surface elevation saved at the boundary of the refined grid were used to supply the boundary conditions for a Flux-Corrected Transport simulation on the refined grid. Previously calibrated global grid effective dispersion coefficients were used in the refined grid simulation.

PREFACE

The Mississippi Sound and Adjacent Areas Study was authorized by congressional resolutions of 1 February 1977 and 10 May 1977. The main purpose of the study as stated in the resolutions is to determine whether the present and proposed dredged material disposal methods for maintenance and construction of the various projects in Mississippi Sound should be modified in any way in the interest of economic efficiency and environmental quality. The resolutions request an investigation by the US Army Corps of Engineers of various dredging techniques and the possibility of developing a coordinated program for the region, with appropriate consideration of ecological factors. The region under study is defined to include the body of water and adjacent land and estuarine areas extending from Chandeleur Sound and Lake Borgne, on the west, along the Mississippi and Alabama coasts to the eastern shore of Mobile Bay, on the east. It is bounded on the north by Interstate Highway 10 and on the south by the 120-ft bottom contour of the Gulf of Mexico.

The numerical model investigation described herein was authorized by the US Army Engineer District, Mobile (SAM). This study was conducted at the US Army Engineer Waterways Experiment Station (WES) in the Wave Dynamics Division (WDD), Hydraulics Laboratory, under the direction of Mr. H. B. Simmons, Chief of the Hydraulics Laboratory, Dr. R. W. Whalin, former Chief of the Wave Dynamics Division, and Mr. C. E. Chatham, Jr., present Chief of the Wave Dynamics Division.

The investigation was performed and this report prepared by Dr. R. A. Schmalz, WDD. Ms. Mary Ann Leggett retuned the Gulf Tide Model in order to provide revised tidal constituent information. Ms. J. I. Jones prepared the geophysical data and developed Appendix A.

The cooperation of and coordination with SAM personnel, including Messrs. Dennis McCann, Maurice James, Dru Barrineau, and Timothy Phillips, enabled the work to remain focused on district needs and provided for an effective transfer of the technology developed. The numerical computations associated with this work were performed on CYBER 175 and CRAY 1 computers located at the Air Force Weapons Laboratory, Kirtland Air Force Base, New Mexico. The numerical model and all datasets were transferred to SAM. WES provided assistance in installing the model on the Boeing Computer System for use by SAM.

Directors of WES during the course of the investigation and the preparation and publication of this report were COL John L. Cannon, CE, COL Nelson P. Conover, CE, COL Tilford C. Creel, CE, and COL Robert C. Lee, CE. Technical Director was Mr. F. R. Brown.

square feet per second	0.09290304	square metres per second
square miles (US statute)	0.4470400	square metres

NUMERICAL MODEL INVESTIGATION OF MISSISSIPPI SOUND AND ADJACENT AREAS

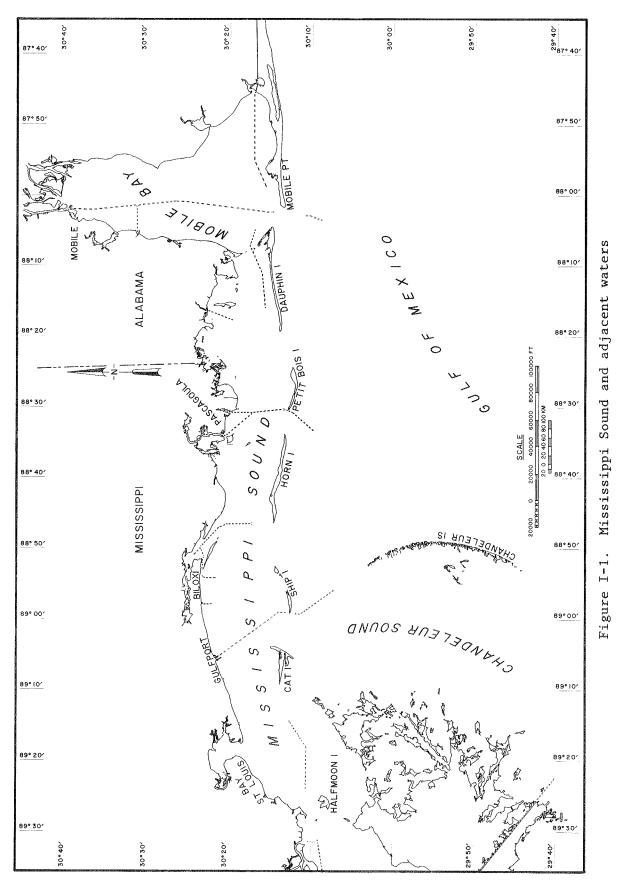

PART I: INTRODUCTION

1. Mississippi Sound and its adjacent waters as shown in Figure I-1 comprise an extremely productive aquatic ecosystem. Major navigation channels maintained by dredge operations within Mississippi Sound are located at Gulfport, Biloxi, and Pascagoula. In order to protect the ecosystem as well as provide for efficient navigation a study was authorized by congressional resolutions of the Senate Committee on Environment and Public Works and the House Committee on Public Works and Transportation. The US Army Engineer District, Mobile, has specific authority and jurisdiction to conduct the study.

2. A numerical modeling approach is required to develop in an efficient manner a quantitative knowledge of tidal circulation and salinity distribution. The US Army Engineer Waterways Experiment Station (WES) was requested to apply WIFM, a two-dimensional vertically integrated model (Butler 1980). In addition, model capability was to be extended to include the prediction of salinity. In order to calibrate and verify the model, Raytheon Ocean Systems was contracted by the Mobile District to collect prototype velocity, temperature, conductivity, and meteorological data. The National Oceanic and Atmospheric Administration (NOAA) was responsible for obtaining tidal elevation data. Texas A&M was contracted to develop a numerical Gulf Tide Model (GTM) to provide accurate tidal elevation information at the boundary of the WIFM model global grid.

3. This report is structured in the following manner.

- <u>a</u>. In Part II, both the Raytheon Ocean System and NOAA Data Collection Programs features are presented. Harmonic analysis results are presented in Part III for both water surface elevations and currents. The GTM is outlined and the results for the O_1 , K_1 , P_1 , M_2 , and S_2 tidal constituents are presented in Part IV. Major features of the salinity algorithm incorporated within WIFM are discussed in Part V in terms of the equations considered, the numerical approximations, and the effective dispersion coefficient formulation.
- <u>b</u>. The remaining parts of this report comprise the numerical modeling effort and are presented in the order in which this work was performed.

- <u>c</u>. Initially, a global grid representing Mississippi Sound and adjacent areas was constructed to interface with the GTM grid encompassing the entire Gulf of Mexico. The development of the global grid depth field, barrier island configuration, freshwater inputs, and location of the gaging stations is presented in Part VI.
- In order to determine periods for study on the global grid, data d. over the entire 180-day survey period were reviewed. Part VII outlines the data review in terms of both hydrodynamic and salinity simulation requirements. Water surface elevation and current tidal constituent constants developed in the harmonic analysis represent astronomic influences only; i.e., all meteorological effects are assumed to be removed in the filtering process employed in the analysis. In contrast, no harmonic analysis was conducted for measured salinity values and, as a result, the meteorological effects have not been removed. The meteorological effects are assumed to consist of wind only; pressure anomalies were not considered. Therefore, in the simulation of salinity, the wind distribution over the grid must also be specified. Since this represents an additional input, salinity simulations were considered after all hydrodynamic simulation work had been completed. The hydrodynamics were considered first on the global and subsequently on a refined grid encompassing the Pascagoula Channel.
- e. In Part VIII the 20-25 September 1980 period is studied in detail in order to identify a suitable time for calibration. The first five days (20-24 September) were selected as the calibration period. In Part IX detailed data for the period 12-16 June 1980 are presented as a separate verification period.
- <u>f</u>. Global grid hydrodynamics are presented in Part X. Bottom friction mechanics are calibrated for the 20-24 September period and subsequently verified for the 12-16 June 1980 period. A hypothetical regional dredge plan involving increasing the size of Sand Island was considered by modifying the depth field in the vicinity of this feature in the global grid. Hydrodynamics for the 20-24 September 1980 period were simulated. By comparing the flow structure with the Sand Island complex in place with the original flow structure it was possible to directly determine the extent of influence of this type of change within the global grid.
- <u>g</u>. The methodology to be employed in constructing refined grids around alternative navigation channel projects is developed in Part XI along with the development of a refined grid around the Pascagoula Ship Channel.
- h. Refined grid hydrodynamics are presented in Part XII. Bottom friction mechanics calibrated and verified on the global grid were employed in a simulation of the 20-24 September 1980 period. Water surface elevations developed in the global grid were used to drive the refined grid boundary.

- 1. All salinity simulation work is presented in Part XIII. The 20-24 September 1980 period was considered. Wind speed and direction were specified as meteorological inputs. A constant drag coefficient of 0.001 was employed to develop the surface wind stress, and the friction mechanism previously developed was used to implement bottom stress. Simulation results for both the Flux-Corrected Transport and the Three Time Level Explicit schemes are presented for the global grid. Effective dispersion coefficients in each coordinate direction were calibrated. The Flux-Corrected Transport global grid salinity levels and water surface elevation saved at the boundary of the refined grid were used to supply the boundary conditions for a Flux-Corrected Transport simulation on the refined grid. Previously calibrated global grid effective dispersion coefficients were used in the refined grid simulation.
- Study conclusions and recommendations for additional simulation j. work are presented in Part XIV. The procedures for constructing the input dataset for the Pascagoula Channel refined grid are outlined in Appendix A. This appendix is intended to provide a guide for District use in developing refined grids encompassing the Biloxi and Gulfport Ship Channels. A general tide generation program is documented in Appendix B. This program was used to generate the predicted tide based on the five major constituents and compare the predicted tide levels with the unfiltered and filtered water levels and currents at each gaging station. In addition, the tide generation portion of the program was incorporated within WIFM in order to generate water surface elevations at the boundary of the global grid. A cubic polynominal feathering technique is presented in Appendix C in order to smoothly transition from the zero elevation and velocity state to the predicted tide levels on the boundary. In order to efficiently specify linearized advection conditions around barrier islands, subroutine ADVBAR was developed as documented in Appendix D and incorporated within WIFM.

4. In the numerical work presented in this report a nested grid modelling philosophy is utilized. Simulation results over the outer nest are used to provide the boundary conditions for the next inner nest. The nesting is taken to level two (GTM drives WIFM global grid, which drives WIFM refined grid). Inherent in this approach is the premise that changes made on the inner grid nest do not cause hydrodynamic and/or salinity fluctuations which propagate to the boundary of the inner grid nest, thereby destroying the integrity of boundary values. As part of this study, in order to demonstrate the validity of this nested grid approach, the region of extent of fluctuations in hydrodynamics and salinity generated by changes in the global grid and refined grids was investigated. Prior to this study, the region of extent of navigation channel induced changes on flow structure was not known. Thus

it was not known whether contemplated deepening and widening alterations for the Biloxi Ship Channel might influence Pascagoula Channel conditions and vice versa. A major concern was that to study any one single channel alteration an extremely large refined grid encompassing all navigation channels would need to be employed. The numerical work presented was focused to address these issues.

PART II: DATA COLLECTION PROGRAM ESTABLISHMENT

5. WES Wave Dynamics Division personnel participated in a series of meetings held at WES with the Mobile District and their consultants to develop prototype data collection requirements for calibration and verification of the numerical model. Preliminary meetings were conducted in March and April 1979 prior to formal study authorization. In March 1980, station locations and data collection procedures were finalized.

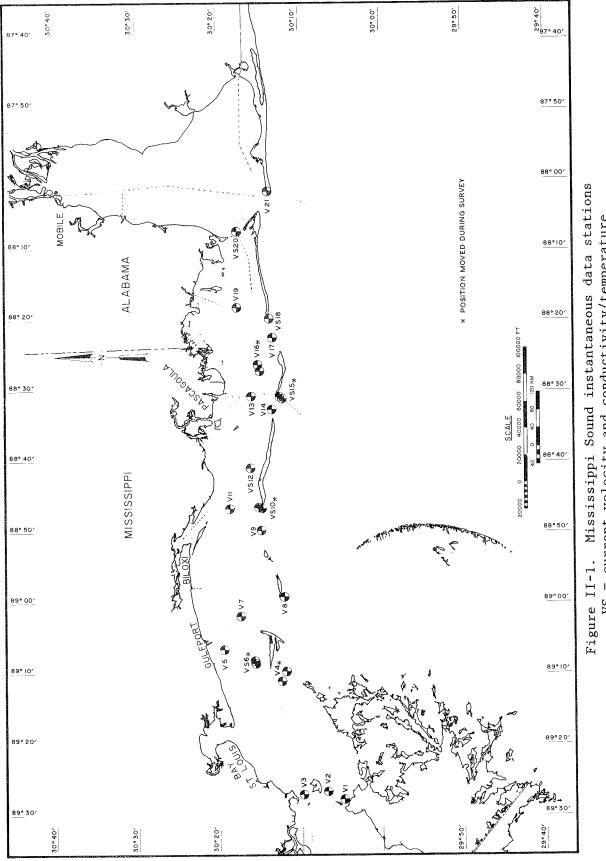

Raytheon Ocean Systems Program

6. Raytheon Ocean Systems collected oceanographic and meteorological data over the period 23 April through 20 October 1980. Approximately 40 current meters and 18 conductivity-temperature instruments were deployed among the 21 stations shown in Figure II-1. Wind speed and direction, air temperature, and air pressure were measured at the five meteorological stations shown in Figure II-2. Bottom pressure measurements were recorded at the three deepsea sites shown in Figure II-3. Salinity and temperature depth profiles were acquired at three-week intervals for the stations shown in Figure II-4. Hydrographic surveys of the barrier island passes, major navigation channels, and bay passes as shown in Figure II-5 were conducted during the period 23 June through 11 July 1980.

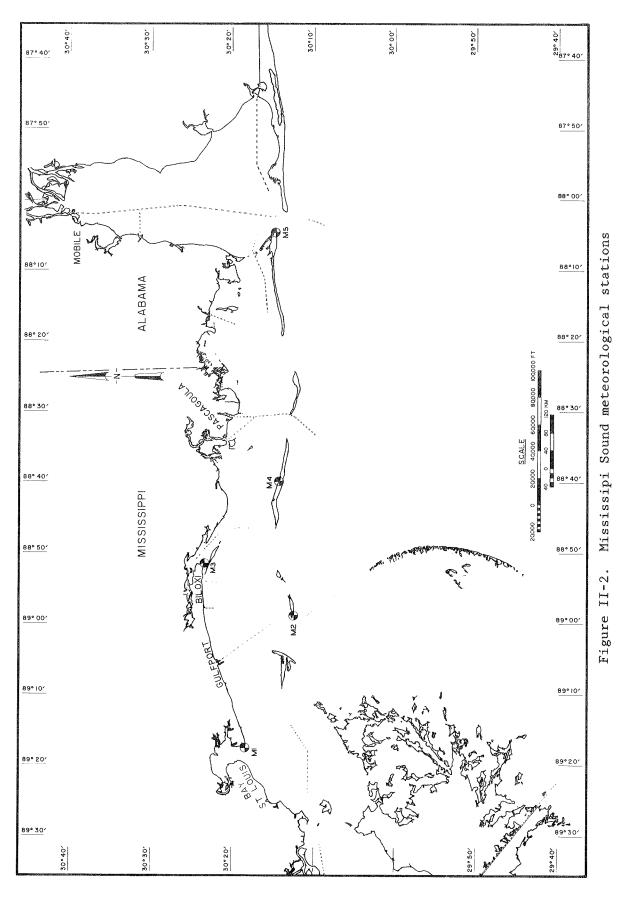

7. Deployment procedures, quality control, data reduction, instrument specifications, and data return are as reported by Raytheon Ocean Systems (1981).

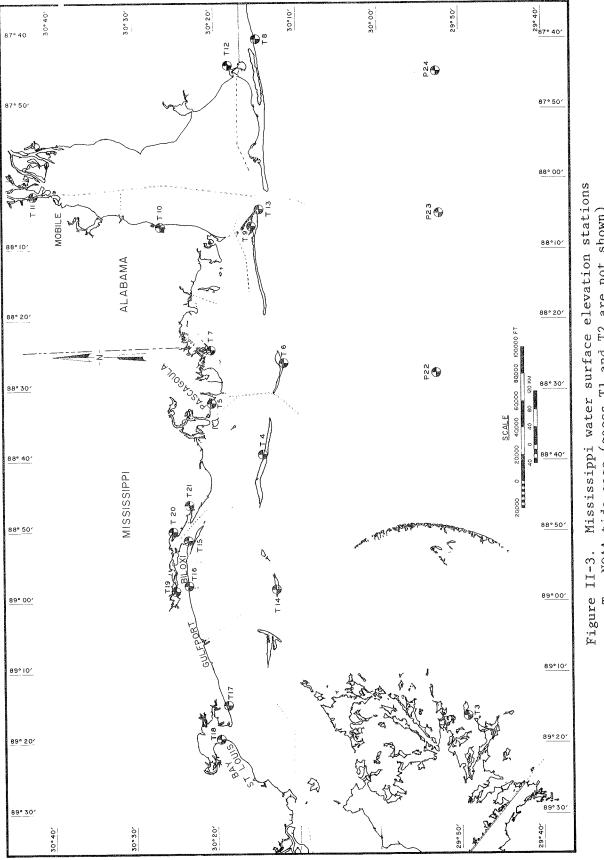

NOAA Data Collection Program

8. NOAA and their contractors obtained tidal elevation data over the April-November 1980 period at the stations shown in Figure II-3. Six-minute and hourly data were edited and furnished to WES on magnetic tape. Tide gage reference levels were connected to NGVD (1929) to provide for a consistent geodetic reference. The relations between mean lower low water (MLLW) and NGVD (1929) as well as the exact station locations are shown in Table II-1.

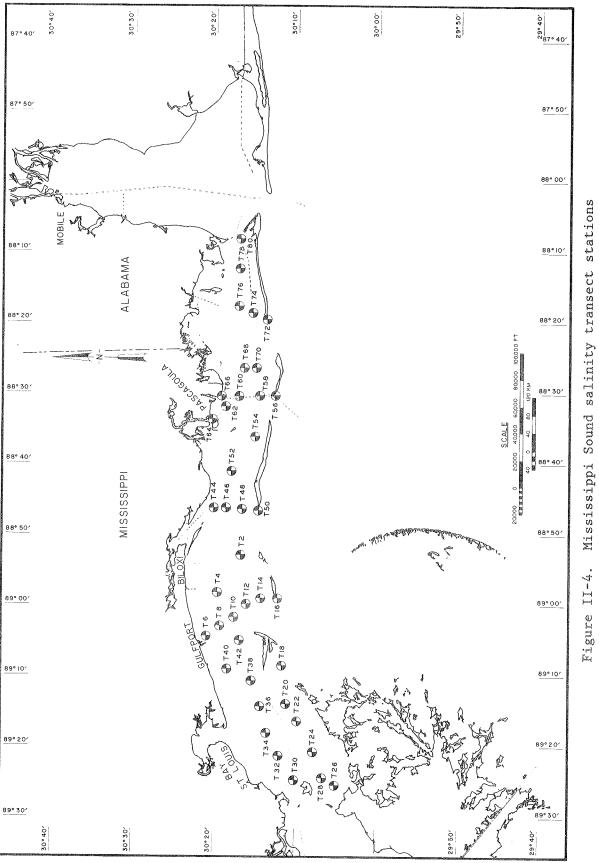

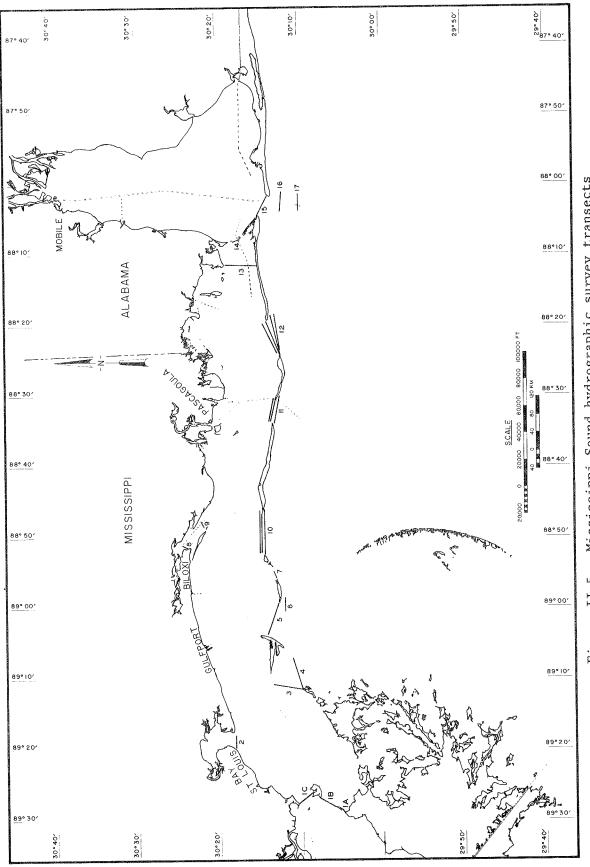

Mississippi Sound hydrographic survey transects Figure II-5.

PART III: PROTOTYPE DATA ANALYSIS

9. A harmonic analysis was performed on both water surface elevation and current data. The analysis techniques are presented in detail by Outlaw (1983). We outline briefly the techniques and results of the analysis for water surface elevations and currents in turn below.

Water Surface Elevations

10. The harmonic analysis for surface elevation tidal constituents was conducted for 22 NOAA tidal elevation stations and three Raytheon pressure cells employing hourly data. Station numbers and locations are as shown in Table II-1. The NOAA stations are representative of tidal elevations in the nearshore region and along the Mississippi Sound barrier islands. The pressure cell data are representative of the tide in the Gulf approximately 27 miles* south of the barrier islands.

- 11. The harmonic analysis included:
 - a. Editing to remove data spikes, insertion of missing data, and subtraction of the mean from the data record.
 - b. Filtering to remove high and low frequency trends from the data.
 - c. Harmonic analysis for tidal constituents.

The NOAA surface elevation data had been edited by NOAA and was continuous over the record length. During the analysis, pressure cell data were converted to surface elevation and corrected for barometric pressure changes prior to removing the mean.

12. A digital band-pass filter was applied to eliminate frequencies in the data outside the semidiurnal to diurnal tidal frequency range.

13. In the harmonic analysis, the tidal elevation at a given station is represented as follows:

$$h(t) = H_{o} + \sum_{i=1}^{n} f_{i}H_{i} \cos \left(\frac{2\pi t}{T_{i}} + (V_{o} + u)_{i} - \kappa_{i}\right)$$

^{*} A table of factors for converting non-SI units of measurement to SI (metric) units is presented on page 12.

where

h(t) = tidal elevation as a function of time t = time $H_{o} = mean of the filtered data record$ $f_{i} = node factor for constituent i$ $(V_{o} + u)_{i} = equilibrium argument for constituent i$ $T_{i} = period for constituent i$ n = number of constituents considered $H_{i} = mean amplitude for constituent i$ $\kappa_{i} = local epoch for constituent i$ The constituents included in the analysis and their periods are:

Harmonic Constituent	Symbol	Period, hr
Principal lunar diurnal	01	25.82
Lunisolar diurnal	K1	23.94
Principal solar diurnal	P1	24.07
Smaller lunar elliptic	M1	24.84
Small lunar elliptic	J1	23.10
Larger lunar elliptic	Q1	26.87
Principal lunar	M2	12.42
Principal solar	S2	12.00
Larger lunar elliptic	N2	12.66

14. The mean amplitude, H_i , and local epoch, κ_i are determined by minimizing the variance between the filtered record and the predicted record given in the equation above.

15. Mean elevations of the NOAA Data Record relative to mean lower low water are given in Table III-1. The constituent amplitude and phases are presented in Tables III-2 and III-3, respectively. The length of the data record and the root mean square (RMS) error are given in Table III-4. The principal tidal constituents are the diurnal constituents 01, K1, P1, and the semi-diurnal constituents M2 and S2.

Currents

16. The harmonic analysis for currents was conducted for all observed data separately for the east-west and north-south components. In this manner analyzed current components correspond in orientation to the numerical model current components thereby facilitating comparisons.

Surface Elevation Record Length and Root Mean Square (RMS) Error

.

 $\star\,$ Refer to Table II-1 for T designations used in Figure II-3.

- 17. The harmonic analysis included:
 - a. Editing of the current data and selecting periods which contained the longest continuous data return.
 - b. Filtering to remove high and low frequency trends.
 - c. Determination of the tidal constituents for both current components.

18. The same harmonic analysis procedures as outlined previously for water surface elevations were employed in the current component analysis. Velocity component means are given in Table III-5. Amplitude and phases for each component are given in Tables III-6 through III-9. In these tables, S, M, and B denote surface, middepth, and bottom meter locations, respectively. At stations where only one meter is located it is denoted by M.

East/West Velocity Component Local Epoch (deg)

Table III-9

PART IV: GULF TIDE MODEL DEVELOPMENT AND RESULTS

19. Consider the depth integrated linearized equations of motion and continuity for a homogeneous and incompressible fluid in spherical coordinates. Reid and Whitaker (1981) have employed alternating direction implicit finite difference approximations to these equations. In an application to the Gulf of Mexico a 15- by 15-minute latitude and longitude grid employing 2228 computational cells has been employed. Wind forcing and stratification effects have not been considered. The tides are forced by direct tide potential and by volume transport (flux) at the Florida Strait and Yucatan Channel.

20. Tidal forcing (flux potential at the two ports and the effective amplitude and phase of the direct tide potential) is determined separately for each of the five major tidal constituents in the Gulf (O_1 , K_1 , P_1 , M_2 , and S_2) by minimizing the sum of the squared errors between the measured constituent amplitude and phase and the model constituent amplitude and phase for all gaging stations. In the original application, Reid and Whitaker considered 20 stations located around the entire Gulf of Mexico. In the least squares analysis, each of the 20 stations was given equal weight. In order to improve results along the northern Gulf coast stretching from Atchafalaya Bay to Pensacola Bay, stations along this coastal segment were weighted more heavily than those occurring outside this segment. The least squares analysis was repeated for all five constituents with the final results for the amplitudes (centimetres) and phases (Greenwich epoch) presented in Tables IV-1 through IV-5 for the O_1 , K_1 , P_1 , M_2 , and S_2 tidal constituents, respectively.

PART V: SALINITY ALGORITHM DEVELOPMENT

21. Salinity is considered as a conservative (passive) constituent. The three-dimensional passive constituent transport equation for laminar flow is presented followed by the modifications necessary for turbulent flow. The turbulent flow equation is depth integrated. The transport equation obtained is then transformed using an exponential stretch. Numerical approximations to the transformed equation are presented followed by the development of relations for the effective dispersion coefficients.

Constituent Transport Equation in Cartesian Coordinates

22. The constituent transport equation is given for laminar flow as

$$\frac{\partial s}{\partial t} + u \frac{\partial s}{\partial x} + v \frac{\partial s}{\partial y} + w \frac{\partial s}{\partial z} = \frac{\partial}{\partial x} \left(D_x \frac{\partial s}{\partial x} \right) + \frac{\partial}{\partial y} \left(D_y \frac{\partial s}{\partial y} \right) + \frac{\partial}{\partial z} \left(D_z \frac{\partial s}{\partial z} \right)$$
(V.1)

where

s = concentration of the material of concern D_x = molecular diffusion coefficient in the x direction D_y = molecular diffusion coefficient in the y direction D_z = molecular diffusion coefficient in the z direction x,y,z = Cartesian coordinates u,v,w = velocity components in the x, y, and z directions, respectively t = time

For a turbulent flow, the eddy dispersion is significantly larger than the molecular diffusion. The following analogous formula holds where time averaging over the time scale of the turbulence has been performed.

$$\frac{\partial s}{\partial t} + u \frac{\partial s}{\partial x} + v \frac{\partial s}{\partial y} + w \frac{\partial s}{\partial z} = \frac{\partial}{\partial x} \left(K_x \frac{\partial s}{\partial x} \right) + \frac{\partial}{\partial y} \left(K_y \frac{\partial s}{\partial y} \right) + \frac{\partial}{\partial z} \left(K_z \frac{\partial s}{\partial z} \right)$$
(V.2)

where K_x , K_y , and K_z are turbulent eddy dispersion coefficients. Equation V.2 may be written in conservation form by adding s times the continuity

equation (namely, zero) to the left-hand side to obtain

$$\frac{\partial s}{\partial t} + \frac{\partial (us)}{\partial x} + \frac{\partial (vs)}{\partial y} + \frac{\partial (ws)}{\partial z} = \frac{\partial}{\partial x} \left(K_x \frac{\partial s}{\partial x} \right) + \frac{\partial}{\partial y} \left(K_y \frac{\partial s}{\partial y} \right) + \frac{\partial}{\partial z} \left(K_z \frac{\partial s}{\partial z} \right) \quad (V.3)$$

This form of the equation is then depth integrated as described in Schmalz (1983a) to obtain:

$$\frac{\partial}{\partial t} (hs) + \frac{\partial}{\partial x} (hus) + \frac{\partial}{\partial y} (hvs) = \frac{\partial}{\partial x} \left(hK_x^* \frac{\partial s}{\partial x} \right) + \frac{\partial}{\partial y} \left(hK_y^* \frac{\partial s}{\partial y} \right)$$
(V.4)

where h is the water depth and $\begin{array}{cc} K^{\star}_{x} & \text{and} & K^{\star}_{y} & \text{are effective dispersion} \\ \text{coefficients.} \end{array}$

Constituent Transport Equation in Transformed Coordinates

23. The transport equation is transformed from x-y space to $\alpha_1^{-\alpha_2}$ space by means of the following coordinate transformation as considered by Butler (1980).

$$x = a_1 + b_1 \alpha_1^c \implies \alpha_1 = \left(\frac{x - a_1}{b_1}\right)^{1/c_1}$$
 (V.5)

$$y = a_2 + b_2 \alpha_2^{c_2} \ge \alpha_2 = \left(\frac{y - a_2}{b_2}\right)^{1/c_2}$$
 (V.6)

Then for an arbitrary hydrodynamic variable $\rho(x,y,t)$

$$\frac{\partial \rho}{\partial x} = \frac{\partial \rho}{\partial \alpha_1} \frac{d\alpha_1}{dx} \qquad \frac{\partial \rho}{\partial y} = \frac{\partial \rho}{\partial \alpha_2} \frac{d\alpha_2}{dy} \qquad (V.7)$$

If we introduce $\mu_1 = dx/d\alpha_1$ and $\mu_2 = dy/d\alpha_2$ then

$$\frac{\partial \rho}{\partial x} = \frac{1}{\mu_1} \frac{\partial \rho}{\partial \alpha_1} \qquad \frac{\partial \rho}{\partial y} = \frac{1}{\mu_2} \frac{\partial \rho}{\partial \alpha_2} \qquad (V.8)$$

 ${\bf \hat{c}}_{ij}$

24. Transforming Equation V.4 in x-y space to $\alpha_1^{-\alpha_2}$ space we obtain the following result.

$$(ds)_{t} + \frac{(dus)_{\alpha_{1}}}{\mu_{1}} + \frac{(dvs)_{\alpha_{2}}}{\mu_{2}} = \frac{1}{\mu_{1}} \left[dK_{\alpha_{1}} \frac{(s)_{\alpha_{1}}}{\mu_{1}} \right]_{\alpha_{1}} + \frac{1}{\mu_{2}} \left[dK_{\alpha_{2}} \frac{(s)_{\alpha_{2}}}{\mu_{2}} \right]_{\alpha_{2}}$$
(V.9)

where d is used to indicate water depth in place of h and

$$()_{t} = \partial/\partial t$$
$$()_{\alpha_{1}} = \partial/\partial \alpha_{1}$$
$$()_{\alpha_{2}} = \partial/\partial \alpha_{2}$$

Equation V.9 is the relation that is the subject of numerical approximation.

Numerical Approximations

25. Schmalz (1983a, 1983b, 1983c) considered several alternate techniques for approximating the linear form of Equation V.9. The Flux-Corrected Transport (FCT) scheme was selected as the most accurate scheme and has been incorporated in the Waterways Experiment Station Implicit Flooding Model (WIFM). In addition a Three Time Level Explicit Transport scheme was also incorporated in the model. A space staggered grid as shown in Figure V.1 was employed in all of the formulations. The datum convention is presented in Figure V.2.

26. Let us introduce the following notation as a prelude to the approximations. Define for an arbitrary variable $F_{n,m}^k$, where $t = k\Delta t$, $y = n\Delta y$, $x = m\Delta x$:

$$\delta_{t}^{k}(F_{n,m}^{k}) = F_{n,m}^{k+1/2} - F_{n,m}^{k}$$
(V.10a)

$$\delta_{t}^{'k}(F_{n,m}^{k}) = F_{n,m}^{k+1} - F_{n,m}^{k}$$
 (V.10b)

$$\delta_{\alpha_1} \left(F_{n,m}^k \right) = F_{n,m+1/2}^k - F_{n,m-1/2}^k$$
(V.10c)

$$\delta_{\alpha_2}(\mathbf{F}_{n,m}^k) = \mathbf{F}_{n+1/2,m}^k - \mathbf{F}_{n-1/2,m}^k$$
(V.10d)

$$\frac{\alpha_1}{F_{n,m}} = \frac{\left(F_{n,m+1/2}^k + F_{n,m-1/2}^k\right)}{2}$$
(V.10e)

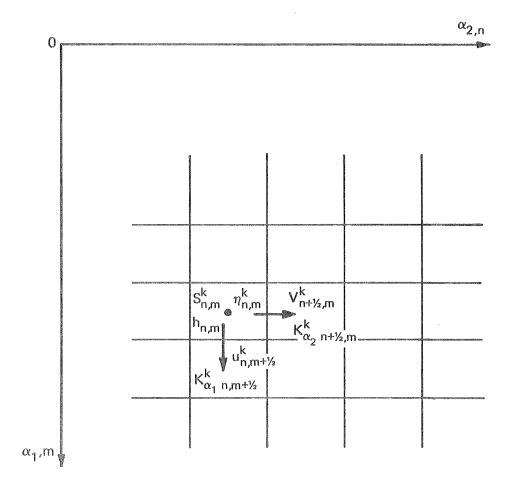

Figure V-1. Space staggered finite difference grid in transformed coordinates

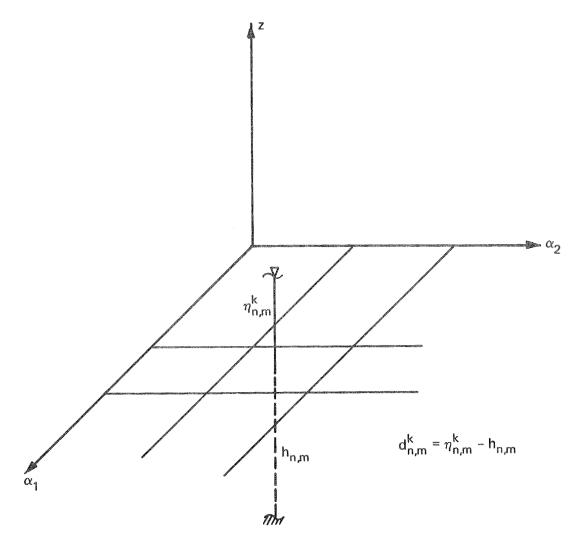

Figure V-2. Datum convention employed within the space staggered grid system

$$\frac{\alpha_2}{F_{n,m}} = \frac{\left(F_{n+1/2,m}^k + F_{n-1/2,m}^k\right)}{2}$$
(V.10f)

Flux-corrected transport

27. Two schemes are used in implementing this approach: a lower order in space nonoscillatory scheme and a higher order in space scheme subject to oscillation. In the method implemented, two time level implicit multioperational ADI schemes were employed. The forward time upwind space (FTUS) and forward time centered space (FTCS) schemes were used as the lower and higher order in space schemes, respectively, and are discussed in turn below. Finally, the necessary flux correction procedures are developed. Leendertse FTCS multioperational scheme

28. The following finite difference equation is considered as an approximation to the nonlinear transport Equation V.9.

$$\delta_{t}^{k}(ds) + \frac{\Delta t}{2\Delta \alpha_{1}(\mu_{1})_{m}} \delta_{\alpha_{1}} \left(\frac{\alpha_{1}}{d} k + 1 \frac{\alpha_{1}}{s} k + 1_{u} k + 1 + \frac{\alpha_{1}}{d} k \frac{\alpha_{1}}{s} k_{u} k \right)$$

$$+ \frac{\Delta t}{2\Delta \alpha_{2}(\mu_{2})_{n}} \delta_{\alpha_{2}} \left(\frac{\alpha_{2}}{d} k + 1 \frac{\alpha_{2}}{s} k + 1_{v} k + 1 + \frac{\alpha_{2}}{d} k \frac{\alpha_{2}}{s} k_{v} k \right)$$

$$- \frac{\Delta t}{2(\Delta \alpha_{1})^{2}(\mu_{1})_{m}} \delta_{\alpha_{1}} \left[\frac{\alpha_{1}}{d} k + 1 \kappa_{\alpha_{1}}^{k+1} \frac{\delta_{\alpha_{1}}(s^{k+1})}{(\mu_{1})_{m}} + \frac{\alpha_{1}}{d} k \kappa_{\alpha_{1}}^{k} \frac{\delta_{\alpha_{1}}(s^{k})}{(\mu_{1})_{m}} \right]$$

$$- \frac{\Delta t}{2(\Delta \alpha_{2})^{2}(\mu_{2})_{n}} \delta_{\alpha_{2}} \left[\frac{\alpha_{2}}{d} k + 1 \kappa_{\alpha_{2}}^{k+1} \frac{\delta_{\alpha_{2}}(s^{k+1})}{(\mu_{2})_{n}} + \frac{\alpha_{2}}{d} k \kappa_{\alpha_{2}}^{k} \frac{\delta_{\alpha_{2}}(s^{k})}{(\mu_{2})_{n}} \right] = 0 \quad \text{at (n,m)}$$

29. The above equation is assumed to be contained within the alternating direction difference equations presented in paragraphs 30 and 31 below. For the linear case obtained for $(\mu_2)_n = (\mu_1)_m = 1$, K_{α_2} , K_{α_1} constants in space and time, and u, v, d constant in space and time, the constituent intermediate time level (k+1/2* in paragraphs 30 and 31) may be eliminated in the alternating direction approach and the total difference equation obtained equals the above difference equation plus some higher order in time factorization terms. The total difference equation is consistent with the linear transport equation. For the nonlinear case considered, it is not possible to eliminate the constituent intermediate time level. Thus the exact form of the factorization terms can not be determined. However, their numerical effect can be tested.

30. The approximations for the X-Sweep may now be written as follows:

$$\delta_{t}^{k}(ds) + \frac{\Delta t \delta_{\alpha_{1}}}{2\Delta \alpha_{1}(\mu_{1})_{m}} \left(\frac{\alpha_{1}}{d^{k+1/2*}} \frac{\alpha_{1}}{s^{k+1/2*}} \frac{\alpha_{1}}{u^{k+1/2*}} \right) \\ - \frac{\Delta t \delta_{\alpha_{1}}}{2\Delta \alpha_{1}^{2}(\mu_{1})_{m}} \left[\frac{\alpha_{1}}{d^{k+1/2*}} \frac{\kappa_{\alpha_{1}}^{k+1/2*}}{\alpha_{1}} \frac{\delta_{\alpha_{1}}}{(\mu_{1})_{m}} \frac{s^{k+1/2*}}{(\mu_{1})_{m}} \right]$$

$$+ \frac{\Delta t}{2(\mu_{2})_{n}\Delta\alpha_{2}} \delta_{\alpha_{2}} \left(\frac{\alpha_{2}}{d^{k}} \frac{\alpha_{2}}{s^{k}} \frac{\alpha_{2}}{v^{k}} \right) \\ - \frac{\Delta t \delta_{\alpha_{2}}}{2\Delta \alpha_{2}^{2}(\mu_{2})_{n}} \left[\frac{\alpha_{1}}{d^{k}} \frac{\kappa_{\alpha_{2}}^{k}}{\kappa_{\alpha_{2}}^{2}} \frac{\delta_{\alpha_{2}}(s^{k})}{(\mu_{2})_{n}} \right] = 0 \quad \text{at (n,m)}$$

If we place all terms at time level K+1/2* on the left-hand side of the equation and expand $K_x = K_{\alpha_1}$, the left-hand side of V.12 is

$$(ds)_{n,m}^{k+1/2*} + \frac{\Delta t}{2\Delta \alpha_{1}(u_{1})_{m}} \left[\frac{\left(n_{n,m+1}^{k+1/2*} - h_{n,m+1} + n_{n,m}^{k+1/2*} - h_{n,m}\right)}{2} u_{n,m+1/2}^{k+1/2*} \frac{\left(s_{n,m+1}^{k+1/2*} + s_{n,m}^{k+1/2*}\right)}{2} - \frac{\left(n_{n,m-1}^{k+1/2*} - h_{n,m-1} + n_{n,m}^{k+1/2*} - h_{n,m}\right)}{2} u_{n,m-1/2}^{k+1/2*} \frac{\left(s_{n,m-1}^{k+1/2*} + s_{n,m}^{k+1/2*}\right)}{2} \right]$$

$$- \frac{\Delta t}{2\Delta \alpha_{1}^{2}(u_{1})_{m}} \left[\frac{\left(n_{n,m+1}^{k+1/2*} - h_{n,m+1} + n_{n,m}^{k+1/2*} - h_{n,m}\right)}{2} \frac{\left(s_{n,m+1}^{k+1/2*} - s_{n,m}^{k+1/2*}\right)}{(u_{1})_{m+1/2}} \kappa_{n,m+1/2}^{k+1/2*} - \frac{\left(n_{n,m-1}^{k+1/2*} - h_{n,m-1} + n_{n,m}^{k+1/2*} - h_{n,m}\right)}{2} \frac{\left(s_{n,m-1}^{k+1/2*} - s_{n,m-1}^{k+1/2*}\right)}{(u_{1})_{m+1/2}} \kappa_{n,m+1/2}^{k+1/2*} \right]$$

$$- \frac{\left(n_{n,m-1}^{k+1/2*} - h_{n,m-1} + n_{n,m-1}^{k+1/2*} - h_{n,m}\right)}{2} \frac{\left(s_{n,m-1}^{k+1/2*} - s_{n,m-1}^{k+1/2*}\right)}{(u_{1})_{m+1/2}} \kappa_{n,m+1/2}^{k+1/2*} \right]$$

Collecting all terms in Equation V.12 at time level $\,k$, denoting the result as $\,B_{m}^{}$, we obtain with $\,K_{y}^{}=K_{\alpha_{2}}^{}$

$$B_{m} := (ds)_{n,m}^{k} - \frac{\Delta t}{2\Delta \alpha_{2}(\mu_{2})_{n}} \left[\frac{\left(n_{n+1,m}^{k} - h_{n+1,m}^{k} + n_{n,m}^{k} - h_{n,m}\right)}{2} v_{n+1/2,m}^{k} \frac{v_{n+1/2,m}^{k}}{2} \frac{\left(s_{n+1,m}^{k} + s_{n,m}^{k}\right)}{2} \right] \\ - \frac{\left(n_{n-1,m}^{k} - h_{n-1,m}^{k} + n_{n,m}^{k} - h_{n,m}\right)}{2} v_{n-1/2,m}^{k} \frac{\left(s_{n-1,m}^{k} + s_{n,m}^{k}\right)}{2} \right] \\ + \frac{\Delta t}{2(\mu_{2})_{n}(\Delta \alpha_{2})^{2}} \left[\frac{\left(n_{n+1,m}^{k} - h_{n+1,m}^{k} + n_{n,m}^{k} - h_{n,m}\right)}{2} \frac{\left(s_{n+1,m}^{k} - s_{n,m}^{k}\right)}{2} \frac{\left(s_{n-1,m}^{k} - s_{n,m}^{k}\right)}{2} \frac{\left(s_{n+1,m}^{k} - s_{n,m}^{k}\right)}{2} \frac{\left(s_{n,m}^{k} - s_{n-1,m}^{k}\right)}{2} \frac{\left(s_{n,m}^{k} - s_{n-1,m}^{k}\right)}{2} \frac{s_{n-1/2}^{k}}{s_{n-1/2}^{k}} \frac{s_{n-1/2,m}^{k}}{s_{n-1/2}^{k}} \frac{s_{n-1/2,m}^{k$$

In Equation V.13 we define $a_{n,m-1}$, $a_{n,m+1}$, and $a_{n,m}$ as follows

$$-a_{n,m-1} = \frac{\Delta t \left(\frac{\alpha_{1}}{d}\right)_{k+1/2*}}{2\Delta \alpha_{1}(\mu_{1})_{m}} \left[\frac{u_{n,m-1/2}^{k+1/2*}}{2} + \frac{(K_{x})_{n,m-1/2}^{k+1/2*}}{\Delta \alpha_{1}(\mu_{1})_{m-1/2}}\right]$$
(V.15)

$$a_{n,m+1} = \frac{\Delta t \binom{\alpha_1}{d}_{n,m+1/2}}{2\Delta \alpha_1 (\mu_1)_m} \left[\frac{u_{n,m+1/2}^{k+1/2*}}{2} - \frac{(K_x)_{n,m+1/2}^{k+1/2*}}{\Delta \alpha_1 (\mu_1)_{m+1/2}} \right]$$
(V.16)

$$a_{n,m} = d_{n,m}^{k+1/2*} + \frac{\Delta t}{2\Delta \alpha_{1}(\mu_{1})_{m}} \left[\frac{\left(\frac{\alpha_{1}}{du}\right)_{k+1/2*}}{2} - \frac{\left(\frac{\alpha_{1}}{du}\right)_{k+1/2*}}{2} \right] + \frac{\Delta t}{2\Delta \alpha_{1}^{2}(\mu_{1})_{m}} \left[\frac{\left(\frac{\alpha_{1}}{dK_{x}}\right)_{n,m+1/2}^{k+1/2*}}{(\mu_{1})_{m+1/2}} + \frac{\left(\frac{\alpha_{1}}{dK_{x}}\right)_{n,m-1/2}^{k+1/2*}}{(\mu_{1})_{m-1/2}} \right]$$
(V.17)

31. Collecting all results we obtain the following interior equation for the X-Sweep $% \left({{{\mathbf{x}}_{\mathrm{s}}} \right)$

$$a_{n,m-1} s_{n,m-1}^{k+1/2*} + a_{n,m} s_{n,m}^{k+1/2*} + a_{n,m+1} s_{n,m+1}^{k+1/2*} = B_{m}$$
 (V.18)

.

32. The approximations for the Y-Sweep may now be written as follows:

$$\delta_{t}^{k+1/2*}(ds) + \frac{\Delta t \,\delta_{\alpha_{2}}}{2\Delta\alpha_{2}(\mu_{2})_{n}} \left(\frac{\alpha_{2}}{d^{k+1}} \frac{\alpha_{2}}{s^{k+1}} v^{k+1} \right) - \frac{\Delta t \,\delta_{\alpha_{2}}}{2\Delta\alpha_{2}^{2}(\mu_{2})_{n}} \left[\frac{\alpha_{2}}{d^{k+1}} \kappa_{\alpha_{2}}^{k+1} \frac{\delta_{\alpha_{2}}(s^{k+1})}{(\mu_{2})_{n}} \right]$$

$$+ \frac{\Delta t \,\delta_{\alpha_{1}}}{2\Delta\alpha_{1}(\mu_{1})_{m}} \left(\frac{\alpha_{1}}{d^{k+1/2*}} \frac{\alpha_{1}}{s^{k+1/2*}} v^{k+1/2*} \right) - \frac{\Delta t \,\delta_{\alpha_{1}}}{2\Delta\alpha_{1}^{2}(\mu_{1})_{m}} \left[\frac{\alpha_{1}}{d^{k+1/2*}} \kappa_{\alpha_{1}}^{k+1/2*} \frac{\delta_{\alpha_{1}}(s^{k+1/2*})}{(\mu_{1})_{m}} \right] = 0 \quad \text{at (n,m)}$$

$$(V.19)$$

Expanding Equation V.19 by employing V.10 and collecting terms at time level k+1 on the left side and leaving terms at time level K+1/2^{*} on the right side the following interior equation for the Y-Sweep is obtained.

$$a_{n-1,m} s_{n-1,m}^{k+1} + a_{n,m} s_{n,m}^{k+1} + a_{n+1,m} s_{n+1,m}^{k+1} = B_n$$
 (V.20)

where $K_x = K_{\alpha_1}$ and $K_y = K_{\alpha_1}$

$$-a_{n-1,m} = \frac{\Delta t \left(\frac{\alpha_2}{d}\right)_{n+1/2,m}^{k+1}}{2\Delta \alpha_2(\mu_2)_n} \left[\frac{v_{n-1/2,m}^{k+1}}{2} + \frac{(K_y)_{n-1/2,m}^{k+1}}{\Delta \alpha_2(\mu_2)_{n-1/2}}\right]$$
(V.21)

$$a_{n+1,m} = \frac{\Delta t \left(\frac{\alpha_2}{d}\right)_{n+1/2,m}^{k+1}}{2\Delta \alpha_2 (\mu_2)_n} \left[\frac{v_{n+1/2,m}^{k+1}}{2} - \frac{(K_y)_{n+1/2,m}^{k+1}}{\Delta \alpha_2 (\mu_2)_{n+1/2}}\right]$$
(V.22)

$$a_{n,m} = d_{n,m}^{k+1} + \frac{\Delta t}{2\Delta \alpha_2(\mu_2)_n} \left[\frac{\left(\frac{\alpha_2}{dv}\right)_{k+1}_{n+1/2,m}}{2} - \frac{\left(\frac{\alpha_2}{dv}\right)_{k+1}_{n-1/2,m}}{2} \right]$$

$$+ \frac{\Delta t}{2\Delta \alpha_{2}^{2}(\mu_{2})_{n}} \left[\frac{\left(\frac{\alpha_{2}}{dK_{y}} \right)_{n+1/2,m}^{k+1}}{(\mu_{2})_{n+1/2}} + \frac{\left(\frac{\alpha_{2}}{dK_{y}} \right)_{n-1/2,m}^{k+1}}{(\mu_{2})_{n-1/2}} \right] \quad (V.23)$$

$$B_{n} = (ds)_{n,m}^{k+1/2*} - \frac{\Delta t}{2(\mu_{1})_{m}\Delta\alpha_{1}} \left[\left(\frac{\alpha_{1}}{ds} \frac{\alpha_{1}}{n} \right)_{n,m+1/2}^{k+1/2*} u_{n,m+1/2}^{k+1/2*} - \left(\frac{\alpha_{1}}{ds} \frac{\alpha_{1}}{n} \right)_{n,m-1/2}^{K+1/2*} u_{n,m-1/2}^{k+1/2*} \right] + \frac{\Delta t}{2(\mu_{1})_{m}(\Delta\alpha_{1})^{2}} \left[\left(\frac{\alpha_{1}}{dK_{x}} \right)_{n,m+1/2}^{k+1/2*} \frac{\left(s_{n,m+1}^{k+1/2*} - s_{n,m}^{k+1/2*} \right)}{(\mu_{1})_{m+1/2}^{k+1/2}} - \left(\frac{\alpha_{1}}{dK_{x}} \right)_{n,m-1/2}^{k+1/2*} \frac{\left(s_{n,m-1/2}^{k+1/2*} - s_{n,m-1}^{k+1/2*} \right)}{(\mu_{1})_{m+1/2}^{k+1/2}} \right]$$
(V.24)

Leendertse FTUS multioperational scheme

33. The following finite difference equation is considered as an approximation to the nonlinear transport Equation V.9:

$$\delta'_{t}^{k}(ds) + \frac{\Delta t}{2\Delta \alpha_{1}(\mu_{1})_{m}} \delta_{\alpha_{1}} \left(\frac{\alpha_{1}}{d} + 1 \frac{u}{s_{1}}^{k+1} u^{k+1} + \frac{\alpha_{1}}{d} \frac{u}{s_{1}}^{k} u^{k} \right)$$

$$+ \frac{\Delta t}{2\Delta \alpha_{2}(\mu_{2})_{n}} \delta_{\alpha_{2}} \left(\frac{\alpha_{2}}{d} + 1 \frac{v}{s_{2}}^{k+1} u^{k+1} + \frac{\alpha_{2}}{d} \frac{v^{k}}{s_{2}} v^{k} \right)$$

$$- \frac{\Delta t}{2(\Delta \alpha_{1})^{2}(\mu_{1})_{m}} \delta_{\alpha_{1}} \left[\frac{\alpha_{1}}{d} + 1 \frac{v^{k+1}}{s_{1}} \frac{\delta_{\alpha_{1}}(s^{k+1})}{(\mu_{1})_{m}} + \frac{\alpha_{1}}{d} \frac{v^{k}}{s_{1}} \frac{v^{k}}{(\mu_{1})_{m}} \right]$$

$$- \frac{\Delta t}{2(\Delta \alpha_{2})^{2}(\mu_{2})_{n}} \delta_{\alpha_{2}} \left[\frac{\alpha_{2}}{d} + 1 \frac{v^{k+1}}{s_{2}} \frac{\delta_{\alpha_{2}}(s^{k+1})}{(\mu_{2})_{n}} + \frac{\alpha_{2}}{d} \frac{v^{k}}{s_{2}} \frac{\delta_{\alpha_{2}}(s^{k})}{(\mu_{2})_{n}} \right] = 0 \quad \text{at (n,m)}$$

34. The following upwind difference operators used in the above equation are defined at (n,m) as follows:

$$\frac{f_{s_{1}}^{k}}{s_{1}^{k}} = \begin{cases} s_{n,m-1/2}^{k} & f_{n,m}^{k} \ge 0 \\ s_{n,m+1/2}^{k} & f_{n,m}^{k} < 0 \end{cases}$$

$$\frac{f_{s_{2}}^{k}}{s_{2}^{k}} = \begin{cases} s_{n-1/2,m}^{k} & f_{n,m}^{k} \ge 0 \\ s_{n+1/2,m}^{k} & f_{n,m}^{k} < 0 \\ s_{n+1/2,m}^{k} & f_{n,m}^{k} < 0 \end{cases}$$
(V.26)

35. For the linear case
$$\left[(\mu_1)_m = (\mu_2)_n = 1.0, K_{\alpha_1}, K_{\alpha_2}, u, v \right]$$

and d constant, the constituent intermediate time level in the alternating direction approach may be eliminated. The difference equation obtained is consistent with the linear transport equation and equals the above difference equations plus some higher order in time factorization terms. For the non-linear case considered here, it is not possible to eliminate the constituent intermediate time level. Therefore the exact form of the factorization terms can not be determined. However, their numerical effect can be assessed.

36. This scheme is similar to the standard ADI technique except that upwind differencing is employed for the advective terms. The necessary modifications for the X-Sweep are shown in Table V-1 and those employed for the Y-Sweep are given in Table V-2.

2.

Flux correction procedures

37. If the factorization terms are ignored, the schemes above may be written in the following flux format.

$$d_{n,m}^{k+1} s_{n,m}^{I} = d_{n,m}^{k} S_{n,m}^{k} - \left[\Delta \alpha_{1}(\mu_{1})_{m} \Delta \alpha_{2}(\mu_{2})_{n} \right]^{-1} \times \left(F_{n+1/2,m}^{I} - F_{n-1/2,m}^{I} + F_{n,m+1/2}^{I} - F_{n,m-1/2}^{I} \right) \quad (V.27)$$

where $t = k\Delta t$, $x = \sum_{i} (\mu_{1})_{i}\Delta\alpha_{1}$, $y = \sum_{i} (\mu_{2})_{i}\Delta\alpha_{2}$ $S_{n,m}^{k} \equiv \text{concentration at location (n,m) at time level k}$ $\Delta\alpha_{1}(\mu_{1})_{m} \equiv x$ space step at m $\Delta\alpha_{2}(\mu_{2})_{m} \equiv y$ space step at n I \equiv general index at time level k+1, which we set to H or L for the higher or lower scheme, respectively $F_{n\pm1/2,m\pm1/2}^{I} \equiv$ fluxes through the appropriate cell faces of cell (n,m). Form is dependent upon the finite difference formulation

We observe from Equation V.27 that the difference between the higher and lower order scheme at (n,m) may be written as follows:

$$\left(S_{n,m}^{H} - S_{n,m}^{L} \right) = - \left[\Delta \alpha_{1}(\mu_{1})_{m} \Delta \alpha_{2}(\mu_{2})_{n} d_{n,m}^{k+1} \right]^{-1} \left[\left(F_{n+1/2,m}^{H} - F_{n+1/2,m}^{L} \right) - \left(F_{n-1/2,m}^{H} - F_{n-1/2,m}^{L} \right) + \left(F_{n,m+1/2}^{H} - F_{n,m+1/2}^{L} \right) \right]$$

$$- \left(F_{n,m-1/2}^{H} - F_{n,m-1/2}^{L} \right) - \left(F_{n,m-1/2}^{H} - F_{n,m-1/2}^{L} \right)$$

$$\left(V.28 \right)$$

Note that this difference can be expressed as an array of fluxes between adjacent grid points and is the condition required for flux correction. We next develop the flux expressions for the higher (F^H) and lower (F^L) order schemes. In order to aid in notation, we make the following definition for an arbitrary variable, F.

$$F_{n,m}^{k+1/2} = \left(F_{n,m}^{k+1} + F_{n,m}^{k}\right) / 2.$$
 (V.29)

38. For the higher order scheme we employ the FTCS scheme written in Equation V.11 in which the factorization terms developed in the multioperational method are not shown. Equation V.11 may be written in the form of V.27, where the total fluxes are presented as the sum of advective and diffusive fluxes.

39. From Equation V.11 one then obtains for the advective fluxes:

$$F_{n\pm1/2,m}^{H} = v_{n\pm1/2,m}^{k+1/2} \Delta t(\mu_{1})_{m} \Delta \alpha_{1} \left[\left(\frac{s^{H} + s^{k}}{2} \right)_{n\pm1,m}^{k+1/2} d_{n\pm1,m}^{k+1/2} + \left(\frac{s^{H} + s^{k}}{2} \right)_{n,m}^{k} d_{n,m}^{k+1/2} \right] / 2. \quad (V.30)$$

$$F_{n,m+1/2}^{H} = u_{n,m+1/2}^{k+1/2} \Delta t(\mu_2)_n \Delta \alpha_2 \left[\left(\frac{s^H + s^k}{2} \right)_{n,m+1} d_{n,m+1}^{k+1/2} + \left(\frac{s^H + s^k}{2} \right)_{n,m} d_{n,m}^{k+1/2} \right] / 2. \quad (V.31)$$

Note the subscript A denotes advection. The diffusive fluxes are then given by the following relations.

$$F_{n\pm1/2,m}^{H_{0}} = \pm K_{y_{n\pm1/2,m}}^{k+1/2} \frac{\Delta t (\mu_{1})_{m} \Delta \alpha_{1}}{2} \times \frac{\left[(s^{H} + s^{k})_{n,m} - (s^{H} + s^{k})_{n\pm1,m} \right]}{\Delta \alpha_{2} (\mu_{2})_{n\pm1/2}} \frac{\left(d_{n\pm1,m}^{k+1/2} + d_{n,m}^{k+1/2} \right)}{2}$$
(V.32)

$$F_{n,m+1/2}^{H_{0}} = \frac{+K_{x_{n,m+1/2}}^{k+1/2}}{\sum_{n,m+1/2}^{\Delta t (\mu_{2})_{n} \Delta \alpha_{2}}} \times \frac{\left[(s^{H} + s^{k})_{n,m} - (s^{H} + s^{k})_{n,m+1} \right]}{\sum_{n,m+1/2}^{\Delta \alpha_{1} (\mu_{1})_{m+1/2}}} \frac{\left(d_{n,m+1}^{k+1/2} + d_{n,m}^{k+1/2} \right)}{2}$$
(V.33)

Note the subscript 0 denotes diffusion.

40. For the lower order scheme, the FTUS scheme written in Equation V.25 is employed. Factorization terms generated by the multioperational method are not considered. Equation V.25 is written in the form of V.27. The total fluxes are presented as the sum of advective and diffusive fluxes.

41. From Equation V.25 one obtains the following set of advective fluxes.

$$F_{n+1/2,m}^{L} = \begin{cases} v_{n+1/2,m}^{k+1/2} \ge 0 & v_{n+1/2,m}^{k+1/2} \Delta t(\mu_{1})_{m} \Delta \alpha_{1} \left(\frac{s^{L} + s^{k}}{2} \right)_{n,m}^{k} d_{n,m}^{k+1/2} \\ & & \\ v_{n+1/2,m}^{k+1/2} < 0 & v_{n+1/2,m}^{k+1/2} \Delta t(\mu_{1})_{m} \Delta \alpha_{1} \left(\frac{s^{L} + s^{k}}{2} \right)_{n+1,m}^{k} d_{n+1,m}^{k+1/2} \end{cases}$$
(V.34)

$$F_{n-1/2,m}^{L_{A}} = \begin{cases} v_{n-1/2,m}^{k+1/2} \ge 0 & v_{n-1/2,m}^{k+1/2} \Delta t (\mu_{1})_{m} \Delta \alpha_{1} \left(\frac{S^{L} + S^{k}}{2} \right)_{n-1,m} d_{n-1,m}^{k+1/2} \\ v_{n-1/2,m}^{k+1/2} < 0 & v_{n-1/2,m}^{k+1/2} \Delta t (\mu_{1})_{m} \Delta \alpha_{1} \left(\frac{S^{L} + S^{k}}{2} \right)_{n,m} d_{n,m}^{k+1/2} \end{cases}$$
(V.35)

$$F_{n,m+1/2}^{L_{A}} = \begin{cases} u_{n,m+1/2}^{k+1/2} \ge 0 & u_{n,m+1/2}^{k+1/2} \Delta t(\mu_{2})_{n} \Delta \alpha_{2} \left(\frac{s^{L} + s^{k}}{2} \right)_{n,m} d_{n,m}^{k+1/2} \\ & & \\ u_{n,m+1/2}^{k+1/2} < 0 & u_{n,m+1/2}^{k+1/2} \Delta t(\mu_{2})_{n} \Delta \alpha_{2} \left(\frac{s^{L} + s^{k}}{2} \right)_{n,m+1} d_{n,m+1}^{k+1/2} \end{cases}$$
(V.36)

$$F_{n,m-1/2}^{L_{A}} = \begin{cases} u_{n,m-1/2}^{k+1/2} \ge 0 & u_{n,m-1/2}^{k+1/2} \Delta t (\mu_{2})_{n} \Delta \alpha_{2} \left(\frac{s^{L} + s^{k}}{2} \right)_{n,m-1} d_{n,m-1}^{k+1/2} \\ u_{n,m-1/2}^{k+1/2} < 0 & u_{n,m-1/2}^{k+1/2} \Delta t (\mu_{2})_{n} \Delta \alpha_{2} \left(\frac{s^{L} + s^{k}}{2} \right)_{n,m} d_{n,m}^{k+1/2} \end{cases}$$
(V.37)

The diffusive fluxes are obtained from Equations V.32 and V.33 with H $\,$ replaced by $\,$ L .

42. The antidiffusive fluxes are then computed as follows.

$$A_{n+1/2,m} = F_{n+1/2,m}^{H} - F_{n+1/2,m}^{L} + F_{n+1/2,m}^{H} - F_{n+1/2,m}^{L}$$
(V.38)

$$A_{n,\underline{m+1/2}} = F_{n,\underline{m+1/2}}^{H} - F_{n,\underline{m+1/2}}^{L} + F_{n,\underline{m+1/2}}^{H} - F_{n,\underline{m+1/2}}^{L} - F_{n,\underline{m+1/2}}^{L}$$
(V.39)

In computing the difference between the diffusive fluxes (third and fourth terms in the above expressions), note that the terms with $S_{n,m}^k$ are of opposite signs and drop out of the equations.

43. Next the maximum and minimum cell values are determined.

$$S_{n,m}^{n} = \max\left(S_{n,m}^{k}, S_{n,m}^{L}\right) \qquad S_{n,m}^{b} = \min\left(S_{n,m}^{k}, S_{n,m}^{L}\right) \qquad (V.40)$$

$$S_{n,m}^{\max} = \max\left(S_{n-1,m}^{a}, S_{n,m}^{a}, S_{n+1,m}^{a}, S_{n,m-1}^{a}, S_{n,m+1}^{a}\right)$$
(V.41)

$$S_{n,m}^{\min} = \min \left(S_{n-1,m}^{b}, S_{n,m}^{b}, S_{n+1,m}^{b}, S_{n,m-1}^{b}, S_{n,m+1}^{b} \right)$$
(V.42)

44. Next the sum of all antidiffusive fluxes into cell (n,m), $P_{n,m}^{\dagger}$, is determined.

$$P_{n,m}^{+} = \max (0, A_{n-1/2,m}) - \min (0, A_{n+1/2,m}) + \max (0, A_{n,m-1/2}) - \min (0, A_{n,m+1/2}) \quad (V.43)$$

The maximum allowable mass into the cell, $Q_{n,m}^{\dagger}$, is then computed as follows:

$$Q_{n,m}^{+} = \left(S_{n,m}^{\max} - S_{n,m}^{L}\right) \left[(\mu_{1})_{m} \Delta \alpha_{1} (\mu_{2})_{n} \Delta \alpha_{2} d_{n,m}^{k+1} \right]$$
(V.44)

45. Similarly, the sum of all antidiffusive fluxes into cell (n,m), $\bar{P_{n,m}}$, is determined.

$$P_{n,m}^{-} = \max (0, A_{n+1/2,m}) - \min (0, A_{n-1/2,m}) + \max (0, A_{n,m+1/2}) - \min (0, A_{n,m-1/2}) \quad (V.45)$$

The maximum allowable mass to leave the cell, $Q_{n,m}$, is then computed.

$$Q_{n,m}^{-} = S_{n,m}^{L} - S_{n,m}^{max} (\mu_{1})_{m} \Delta \alpha_{1} (\mu_{2})_{n} \Delta \alpha_{2} d_{n,m}^{k+1}$$
(V.46)

46. The following ratios are next computed for use in determining the limiting coefficients.

•

$$R_{n,m}^{+} = \begin{cases} \min(1, Q_{n,m}^{+} / P_{n,m}^{+}) & P_{n,m}^{+} > 0 \\ 0 & P_{n,m}^{+} = 0 \end{cases}$$
(V.47)

$$R_{n,m}^{-} = \begin{cases} \min(1, Q_{n,m}^{-} / P_{n,m}^{-}) & P_{n,m}^{-} > 0 \\ 0 & P_{n,m}^{-} = 0 \end{cases}$$
(V.48)

The limiting coefficients are then given by

$$C_{n+1/2,m} = \begin{cases} \min(R_{n+1,m}^+, R_{n,m}^-) & A_{n+1/2,m} \ge 0 \\ \min(R_{n,m}^+, R_{n+1,m}^-) & A_{n+1/2,m} < 0 \end{cases}$$

(V.49)

,

$$C_{n,m+1/2} = \begin{cases} \min \left(R_{n,m+1}^{+}, R_{n,m}^{-} \right) & A_{n,m+1/2} \ge 0 \\ \min \left(R_{n,m}^{+}, R_{n,m+1}^{-} \right) & A_{n,m+1/2} < 0 \end{cases}$$

47. The antidiffusive fluxes in Equations V.38 and V.39 are limited by multiplying by the limiting coefficients and the solution is advanced to the next time level.

$$s_{n,m}^{k+1} = s_{n,m}^{L} - \left[\Delta \alpha_{1}(\mu_{1})_{m} \Delta \alpha_{2}(\mu_{2})_{n} d_{n,m}^{k+1} \right]^{-1} (C_{n+1/2,m}^{A} + 1/2,m)$$
$$- C_{n-1/2,m}^{A} - 1/2,m + C_{n,m+1/2}^{A} + C_{n,m+1/2}^{A} + 0,m + 1/2 - C_{n,m-1/2}^{A} + 0,m + 1/2 - 0,m +$$

48. The coding of the flux-corrected transport procedures is contained in Subroutine CONC in the numerical model.

Three Time Level Explicit scheme

49. In order to avoid the averaging of hydrodynamic quantities which is performed when employing a two time level transport scheme, with a three time level velocity scheme, a three time level explicit scheme is considered.

50. It is instructive to observe the form of the continuity equation employed in the multioperational (alternating direction) hydrodynamic scheme.

X - Sweep

$$\frac{1}{2\Delta t} \left(\eta^{\star} - \eta^{k-1} \right)_{n,m} + \frac{1}{2(\mu_1)_m^{\Delta \alpha_1}} \left[\left(u^{k+1} + u^{k-1} \right) \frac{\alpha_1}{d^k} \right|_{n,m+1/2} - \left(u^{k+1} + u^{k-1} \right) \frac{\alpha_1}{d^k} \right|_{n,m-1/2} \right] \\ + \frac{1}{(\mu_2)_n^{\Delta \alpha_2}} \left[v^{k-1} \frac{\alpha_2}{d^k} \right|_{n+1/2,m} - v^{k-1} \frac{\alpha_2}{d^k} \right]_{n-1/2,m} = 0 \quad \text{at } (n,m)$$
(V.51)

with

$$\frac{\alpha_1}{d_{n,m\pm 1/2}} = d_{n,m\pm 1}^k + d_{n,m}^k$$

$$\frac{\alpha_2}{d_{n\pm 1/2,m}} = d_{n\pm 1,m}^k + d_{n,m}^k$$

N

and

$$d_{n,m}^{k} = \eta_{n,m}^{k} - h_{n,m}$$

Y - Sweep:

$$\frac{1}{2\Delta t} \left(\eta_{n,m}^{k+1} - \eta_{n,m}^{\star} \right) + \frac{1}{2 \left(\mu_2 \right)_n^{\Delta \alpha_2}} \left[\left(v^{k+1} - v^{k-1} \right) \frac{\alpha_2}{d^k} \Big|_{n+1/2,m} - \left(v^{k+1} - v^{k-1} \right) \frac{\alpha_2}{d^k} \Big|_{n-1/2,m} \right] = 0$$

at (n,m) (V.52)

where

 $\begin{array}{l} \Delta t = \text{time step length} \\ \eta^{\star} = \text{water surface elevation at intermediate time level}^{\star} \\ \eta^{k-1}_{n,m} = \text{water surface elevation at time level } k - 1 \text{ at cell } (n,m) \\ \Delta \alpha_1 = \alpha_1 \quad \text{space increment} \\ \Delta \alpha_2 = \alpha_2 \quad \text{space increment} \\ u^{k+1}_{n,m+1/2} = x - \alpha_1 \quad \text{velocity component at time level } k + 1 \quad \text{at cell } (n,m) \\ u^{k-1}_{n,m+1/2} = x - \alpha_1 \quad \text{velocity component at time level } k - 1 \quad \text{at cell } (n,m) \\ v^{k+1}_{n+1/2,m} = y - \alpha_2 \quad \text{velocity component at time level } k + 1 \quad \text{at cell } (n,m) \\ v^{k-1}_{n+1/2,m} = y - \alpha_2 \quad \text{velocity component at time level } k + 1 \quad \text{at cell } (n,m) \\ v^{k-1}_{n+1/2,m} = y - \alpha_2 \quad \text{velocity component at time level } k - 1 \quad \text{at cell } (n,m) \\ d^{k}_{n,m} = \text{water depth at time level } k \quad \text{at cell } n,m \end{array}$

If we eliminate the intermediate level η^{\star} ; e.g., solve for η^{\star} in Equation V.51 and substitute in V.52, we obtain:

$$\frac{\left(\eta_{n,m}^{k+1} - \eta_{n,m}^{k-1}\right)}{2\Delta t} + \frac{1}{2\left(\mu_{1}\right)_{m}^{\Delta\alpha_{1}}} \left[\left(u^{k+1} + u^{k-1}\right) \frac{\alpha_{1}}{d}k \Big|_{n,m+1/2} - \left(u^{k+1} + u^{k-1}\right) \frac{\alpha_{1}}{d}k \Big|_{n,m-1/2} \right] \\ + \frac{1}{2\left(\mu_{2}\right)_{n}^{\Delta\alpha_{2}}} \left[\left(v^{k+1} + v^{k-1}\right) \frac{\alpha_{2}}{d}k \Big|_{n+1/2,m} - \left(v^{k+1} + v^{k-1}\right) \frac{\alpha_{2}}{d}k \Big|_{n-1/2,m} \right] = 0$$

$$(V.53)$$
at (n,m)

Since $d_{n,m}^{k} = \eta_{n,m}^{k} - h_{n,m}$ Equation V.53 is a full three time level scheme. In order to develop a three time level volume consistent transport scheme, we replace $d_{n,m}^{k}$ in Equation V.53 with $d_{n,m}^{k} S_{n,m}^{k}$ and thereby obtain:

$$\frac{\left(\frac{d^{k+1}s^{k+1}_{n,m} - d^{k-1}s^{k-1}_{n,m}s^{k-1}_{n,m}\right)}{2\Delta t} + \frac{1}{2\left(\mu_{1}\right)_{m}\Delta\alpha_{1}}\left[\left(u^{k+1} + u^{k-1}\right)\frac{\alpha_{1}}{d^{k}}\frac{\alpha_{1}}{s^{k}}\right]_{n,m+1/2} - \left(u^{k+1} + u^{k-1}\right)\frac{\alpha_{1}}{d^{k}}\frac{\alpha_{1}}{s^{k}}\right]_{n,m-1/2}\right] \\ + \frac{1}{2\left(\mu_{2}\right)_{n}\Delta\alpha_{2}}\left[\left(v^{k+1} + v^{k-1}\right)\frac{\alpha_{2}}{d^{k}}\frac{\alpha_{2}}{s^{k}}\right]_{n+1/2,m} - \left(v^{k+1} + v^{k-1}\right)\frac{\alpha_{2}}{d^{k}}\frac{\alpha_{2}}{s^{k}}\right]_{n-1/2,m}\right]$$

$$= + \frac{1}{\left(\mu_{1}\right)_{m}\left(\Delta\alpha_{1}\right)^{2}}\left[\frac{\alpha_{1}}{d^{k-1}}\kappa_{\alpha_{1}}^{k-1}\right]_{n,m+1/2} \frac{\left(s^{k-1}_{n,m+1} - s^{k-1}_{n,m}\right)}{\left(\mu_{1}\right)_{m+1/2}} - \frac{\alpha_{1}}{d^{k-1}}\kappa_{\alpha_{1}}^{k-1}\right]_{n,m-1/2} \frac{\left(s^{k-1}_{n,m} - s^{k-1}_{n,m-1}\right)}{\left(\mu_{1}\right)_{m-1/2}}\right] \\ + \frac{1}{\left(\mu_{2}\right)_{n}\left(\Delta\alpha_{2}\right)^{2}}\left[\frac{\alpha_{2}}{d^{k-1}}\kappa_{\alpha_{2}}^{k-1}\right]_{n+1/2,m} \frac{\left(s^{k-1}_{n+1,m} - s^{k-1}_{n,m}\right)}{\left(\mu_{2}\right)_{n+1/2}} - \frac{\alpha_{2}}{d^{k-1}}\kappa_{\alpha_{2}}^{k-1}\right]_{n-1/2,m} \frac{\left(s^{k-1}_{n,m} - s^{k-1}_{n-1,m}\right)}{\left(\mu_{2}\right)_{n-1/2}}\right]$$

The scheme in Equation V.54 employs centered space differencing of the advective terms (FTCS). Alternatively, one may employ upwind differencing (FTUS). The two schemes FTCS and FTUS might then be employed in a fluxcorrected transport procedure.

51. In order to analyze the stability of these schemes, we consider the linear case, $d_{n,m}^k = d$, $u_{n,m\pm 1/2}^k = u$, $v_{n\pm 1/2,m}^k = v$, $K_{\alpha_1}^{k-1} = K_x$, and $K_{\alpha_2}^{k-1} = K_y$. Also $(\mu_1)_m = (\mu_2)_m = 1$.

52. Let us consider the following general three time level transport scheme written in operator form, where

$$\delta_{2t}(s_{n,m}^{k}) = (s_{n,m}^{k+1} - s_{n,m}^{k-1})/2\Delta t$$

$$\delta_{x}(s_{n,m}^{k}) = (s_{n,m+1}^{k} - s_{n,m-1}^{k})/2\Delta x$$

$$\delta_{y}(s_{n,m}^{k}) = (s_{n+1,m}^{k} - s_{n-1,m}^{k})/2\Delta y$$

$$\delta_{x}^{2}(s_{n,m}^{k}) = (s_{n,m+1}^{k} + s_{n,m-1}^{k} - 2s_{n,m}^{k})/\Delta x^{2}$$

$$\delta_{y}^{2}(s_{n,m}^{k}) = (s_{n+1,m}^{k} + s_{n-1,m}^{k} - 2s_{n,m}^{k})/\Delta y^{2}$$

$$\delta_{2t}\left(s_{n,m}^{k}\right) + u\left(\overbrace{\delta_{x} + g \frac{\Delta x}{2} \delta_{x}^{2}}^{T} \right)\left(s_{n,m}^{k}\right) + v\left(\overbrace{\delta_{y} + g \frac{\Delta y}{2} \delta_{y}^{2}}^{T} \right)\left(s_{n,m}^{k}\right) - K_{x}\delta_{x}^{2}\left(s_{n,m}^{k-1}\right) - K_{y}\delta_{y}^{2}\left(s_{n,m}^{k-1}\right) = 0 \text{ at } (n,m) \quad (V.55)$$

with $g\epsilon(-1, 0, 1)$

Note: If g = o, central differencing of the advective terms is affected. If u, v > o g = -1 (backward differencing) is employed. If u, v < o, g = +1 (forward differencing) is employed. This method constitutes upwind differencing.

53. We note that Equation V.55 is a three time level scheme, thus in order to perform a stability analysis we set up a second variable $V_{n,m}^k$ and

set $V_{n,m}^{k+1} = S_{n,m}^{k}$, then Equation V.55 may be written in matrix form as follows: $\begin{bmatrix} S_{n,m}^{k+1} \\ V_{n,m}^{k+1} \end{bmatrix} = \begin{bmatrix} -2\Delta t (uT_x + vT_y) + 2\Delta t (K_x \delta_x^2 + K_y \delta_y^2) + 1 \\ 1 & 0 \end{bmatrix} \begin{bmatrix} S_{n,m}^{k} \\ V_{n,m}^{k} \end{bmatrix}$ (V.56)

54. Equation V.56 is in the required format for a stability analysis. Following standard practice, assume $S_{n,m}^k = e^{k\alpha\Delta t} e^{n\gamma\Delta y} e^{m\beta\Delta x}$

55. Thus we may develop the following supplemental relations:

$$T_{x}(S_{n,m}^{k}) \equiv \left(\frac{i}{\Delta x} \sin \beta \Delta x - \frac{2g}{\Delta x} \sin^{2} \frac{\beta \Delta x}{2}\right) S_{n,m}^{k}$$

$$T_{y}(S_{n,m}^{k}) \equiv \left(\frac{i}{\Delta y} \sin \gamma \Delta y - \frac{2g}{\Delta y} \sin^{2} \frac{\gamma \Delta y}{2}\right) S_{n,m}^{k}$$

$$\delta_{x}^{2}(S_{n,m}^{k}) \equiv \frac{-4}{\Delta x^{2}} \sin^{2} \frac{\beta \Delta x}{2}$$

$$\delta_{y}^{2}(S_{n,m}^{k}) \equiv \frac{-4}{\Delta y^{2}} \sin^{2} \frac{\beta \Delta x}{2}$$
(V.57)

Thus we obtain for Equation V.56, the following matrix equation:

$$\begin{bmatrix} S_{n,m}^{k+1} \\ V_{n,m}^{k+1} \\ V_{n,m}^{k+1} \end{bmatrix} = \begin{bmatrix} -2 \begin{bmatrix} C_x & i\left(\sin \beta \Delta x - 2g \sin^2 \frac{\beta \Delta x}{2}\right) & -8 \left(D_x \sin^2 \frac{\beta \Delta x}{2} + D_y \sin^2 \frac{\gamma \Delta y}{2}\right) + 1 \\ + C_y & \left(i \sin \gamma \beta y - 2g \sin^2 \frac{\gamma \Delta y}{2}\right) \end{bmatrix} & 0 \end{bmatrix} \begin{bmatrix} S_{n,m}^k \\ V_{n,m}^k \end{bmatrix}$$
(V.58)

with

$$C_x = u\Delta t/\Delta x$$
 $C_y = v\Delta t/\Delta t$ $D_x = \frac{K_x \Delta t}{\Delta x^2}$ $D_y = \frac{K_y \Delta t}{\Delta y^2}$

In order to achieve stability all the eigenvalues of A must be less than 1 in magnitude. To compute the eigenvalues, the following charactertistic equation is used.

$$|A - \lambda I| = 0$$

$$\lambda^{2} + \lambda \left[C_{x} \left(2i \sin \beta \Delta x - 4g \sin^{2} \frac{\beta \Delta x}{2} \right) + C_{y} \left(2i \sin \gamma \Delta y - 4g \sin^{2} \frac{\gamma \Delta y}{2} \right) \right] \qquad (V.59)$$

$$-1 + \left(8D_{x} \sin^{2} \frac{\beta \Delta x}{2} + 8D_{y} \sin^{2} \frac{\gamma \Delta y}{2} \right) = 0$$

In considering Equation V.59, let us introduce the following supplemental variables:

$$a = C_{x} \left(2i \sin \beta \Delta x - 4g \sin^{2} \frac{\beta \Delta x}{2} \right) + C_{y} \left(2i \sin \gamma \Delta y - 4g \sin^{2} \frac{\gamma \Delta y}{2} \right)$$

$$b = 8D_{x} \sin^{2} \frac{\beta \Delta x}{2} + D_{y} \sin^{2} \frac{\gamma \Delta y}{2}$$
(V.60)

Then Equation V.59 becomes

$$\lambda^2 + 2a + (b - 1) = 0 \tag{V.61}$$

Using the quadratic equation formula:

$$\lambda_{1,2} = \frac{-a \pm \sqrt{a^2 - 4(b - 1)}}{2} = \frac{-a}{2} \pm \sqrt{\left(\frac{a}{2}\right)^2 + 1} = b$$
(V.62)

56. To find restrictions on $C_x C_y$, D_x , and D_y such that $|\lambda_{1,2}| < 1$ appears to be difficult for this case.

57. Instead, we consider the ranges of C_x , C_y , D_x , and D_y for the Mississippi Sound case. Consider the following maximum velocity and dispersion conditions in Mississippi Sound: u = v = 3 fps, $K_x = K_y$ = 100 ft²/sec. Since on the global grid the minimum cell dimensions are $\Delta x = \Delta y = 3500$ ft and a time step $\Delta t = 360$ sec is employed, bounds on the supplemental relations in Equation V.53 become C_x , $C_y < 0.3$ and D_x , $D_y < 0.003$.

 γ_{m} 58. Let us introduce $\beta_{m} = 2\pi/m\Delta x$ and $\gamma_{n} = 2\pi/n\Delta y$ and consider the wave numbers n and m to vary from 2-9 over 3 log cycles. We compute the eigenvalue for each set of wave numbers n and m as follows:

$$a = C_{x} \left(2i \sin \frac{2\pi}{m} - 4g \sin^{2} \frac{\pi}{m} \right) + C_{y} \left(2i \sin \frac{2\pi}{n} - 4g \sin^{2} \frac{\pi}{n} \right)$$

$$b = 8 \left(D_{x} \sin^{2} \frac{\pi}{m} + D_{y} \sin^{2} \frac{\pi}{n} \right)$$

$$\lambda_{1,2} = -\frac{a}{2} \pm \sqrt{\left(\frac{a}{2}\right)^{2} + 1 - 6}$$

(V.63)

59. The computer program employing Equation V.62 shown in Table V-3 was used to compute the eigenvalues for the general transport scheme. The results are shown in Table V-4 for the cases considered. Case III represents the conditions to be considered within Mississippi Sound. Since the upward scheme is unstable, it may not be employed as the lower order scheme in the fluxcorrected transport method.

60. Although it is possible to flux-correct the three time level centering of the advective terms scheme, this was not undertaken in this study. This three level scheme with the advective terms centered in time was coded as Subroutine CONCE within the model, thereby allowing the model user an alternate scheme to employ in the transport calculations. This scheme may be employed for transport simulations in which the constituent levels are reasonably uniform. For sharp front problems, the Flux-Corrected Transport Scheme should be used.

Dispersion Coefficient Formulation

61. To close the numerical approximations to the two-dimensional depth averaged transport equation, relations for the effective dispersion coefficients must be developed in terms of flow field properties.

62. The effective dispersion coefficients are assumed to have the following forms:

$$K_{x}^{*} = C_{x}\sqrt{g} \frac{|\mathbf{u}|\mathbf{h}}{C} \leftarrow D_{x} ; \quad K_{y}^{*} = C_{y}\sqrt{g} \frac{|\mathbf{v}|\mathbf{h}}{C} + D_{y}$$
(V.64)

where

K* , K* = effective dispersion coefficients in the x and y directions
 g = acceleration due to gravity

u, v = velocity components in the x and y directions, respectively

Eigenvalue Analysis Results for the General Three Time Level Explicit Scheme

Table V-4

h = water depth

C = Chezy coefficient

 C_x , C_y = dispersion factors in the x and y directions, respectively D_x , D_y = dispersion offsets due to wind effects in the x and y directions, respectively, $(D_x, D_y > 0)$

63. Elder (1959) has determined the longitudinal and lateral dispersion coefficients in open channel flow experiments to be given by the following relations

$$K_{\rm L} = 5.93 \text{ hu*}$$
 $K_{\rm LA} = 0.23 \text{ hu*}$ (V.65)

where

KLA = lateral dispersion coefficient
KL = longitudinal dispersion coefficient
h = water depth (hydraulic radius)
u* = shear (friction) velocity

For open channel flow, the following relations hold:

$$u^{\star} = \sqrt{ghS_e}$$
 $u = C\sqrt{hS_e}$ (V.66)

where

u* ≡ friction velocity g ≡ acceleration of gravity h ≡ water depth S_e ≡ slope of energy grade line C ≡ Cheźy coefficient

As a result, we obtain:

$$u_{\star} = \sqrt{g} \frac{u}{c} \tag{V.67}$$

where

u ≡ velocity g ≡ gravity C ≡ Cheźy coefficient

Therefore, Equation V.65 becomes

$$K_{L} = 5.93\sqrt{g} \frac{uh}{C} \qquad K_{LA} = 0.23\sqrt{g} \frac{uh}{C} \qquad (V.68)$$

64. Taylor (1954) has conducted pipe flow experiments to determine the longitudinal dispersion coefficient. By assuming the hydraulic radius as half the pipe radius in the pipe experiments and equal to the water depth in a uniform steady flow open channel, the coefficient in the longitudinal dispersion coefficient equation (V.68) is determined to be 20.2 rather than 5.93.

65. For one-dimensional flow in the x direction, $C_x \varepsilon$ (5.93, 20.2) and $C_y = 0.23$. In order to extrapolate these results to a two-dimensional flow as occurs in Mississippi Sound C_x , C_y , D_x , D_y are specified for each grid cell. The cell face conditions for each cell are examined independently in each coordinate direction. For a no-flow cell face condition, C_x and D_x or C_y and D_y are set to zero. (No dispersion may occur across a solid boundary.) For a flow cell face condition on the u-velocity cell face (see Figure A-1), the second digit in the u-velocity cell face flag is examined. If advection is not allowed, C_x is reduced by a user specified factor, F. For a flow cell face condition on the v-velocity cell face (see Figure A-1), analogous procedures are employed.

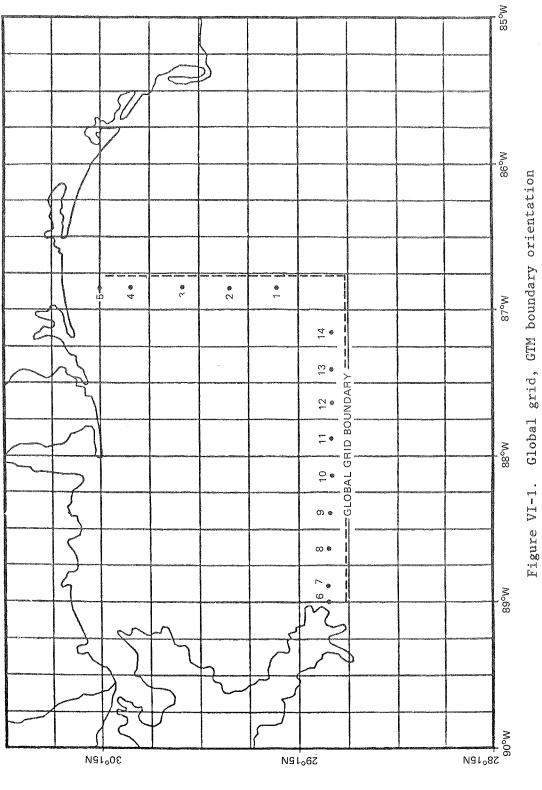

66. In order to calibrate the effective dispersion coefficients, C_x , D_x , C_y , D_y , specified on a cell-by-cell basis, and F are adjusted until simulated salinity levels correspond to measured salinity levels. Based upon experimental results, C_x , $C_y \varepsilon$ (5.93, 20.2) F ~ 0.23/5.93 = 0.0388. The wind effect terms D_x and D_y are more difficult to determine. Leendertse (1970, 1971) in a simulation of Jamaica Bay suggested D_x , $D_y \varepsilon$ (25, 45) ft²/sec. Since the velocity magnitudes u and v in Equation V.64 will increase with increasing wind speeds, the effective dispersion coefficients will increase without considering D_x and D_y . For this reason, D_x and D_y will be set to zero, and C_x , C_y , and F will be adjusted during the calibration process.

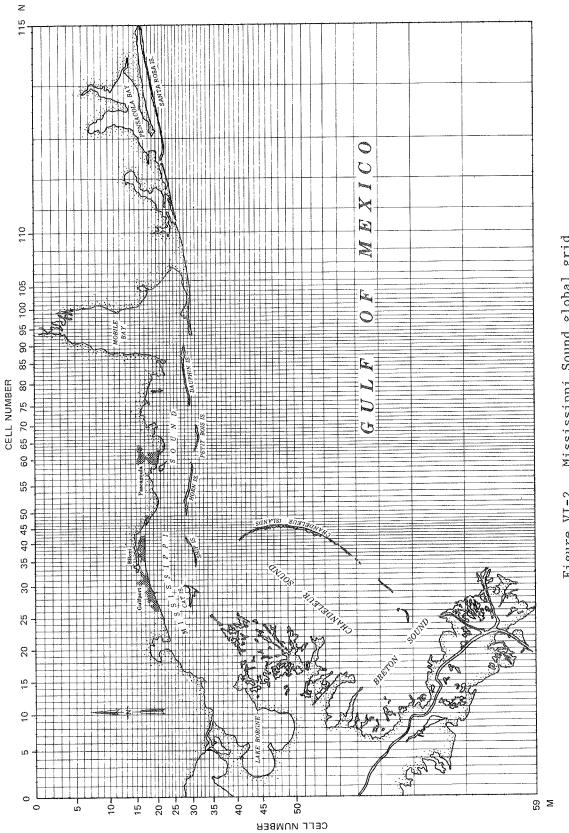

PART VI: DEVELOPMENT OF A GLOBAL GRID FOR MISSISSIPPI SOUND

67. The hydrodynamic salinity model developed in this study employs a variable (exponentially stretched) computational grid. In transforming real space to computational space, each coordinate axis is mapped independently using Program MAPIT. This enables the specification of partition points along each axis. These partition points coincide with the location of barrier island passes and the shoreline.

68. The grid spacing along the southern and eastern extents of the global grid as shown in Figure VI-1 was set to correspond to the 15-min latitude and longitude uniform grid employed in the GTM. In this manner, interpolation in only one space dimension is required in developing the global grid boundary conditions. This consideration established an upper bound on the grid spacing in each direction. The lower bound in grid spacing was obtained such that grid cell aspect ratios would be no larger than 20 and explicit time-step limitations would not be severe. Considerable engineering judgment and consultation with the Mobile District was exercised in developing the global grid.

69. The grid developed extends in geographical extent from the western end of Lake Borgne to Santa Rosa Island in the west-east orientation and from the Mississippi River Delta to above Mobile Bay in the north-south orientation. The east-west extent employs 116 lines and the north-south 60 lines, resulting in a grid of 6785 (115 \times 59) computational cells as shown in Figure VI-2. Minimum spatial resolution of approximately 3500-4000 ft is obtained within the passes into Mississippi Sound and within the Sound itself. Depths within Mississippi Sound are relatively shallow (10-20 ft), except in the navigation channels, which are normally maintained at 30-35 ft. As a result, the gravity wave speed within the sound is <38 fps, resulting in an explicit time-step limitation of approximately 100 sec. All numerical simulations employ a 360-sec (6 min) time step, resulting in a maximum spatial Courant number of less than 4 within the Sound. The mapping for the horizontal (east-west) orientation is presented in Table VI-1. The mapping for the vertical (north-south) orientation is given in Table VI-2. The grid obtained is presented in Figure VI-2. In Tables VI-1 and VI-2, the real space values are in map inches as measured from the maps shown in Table VI-3 below.

Mississippi Sound global grid Figure VI-2.

Initial Depth Assignment

70. Program TGRID was employed to plot subgrids corresponding to grid areas shown on the individual nautical charts as shown in Table VI-4. Each subgrid was next overlaid on its corresponding nautical chart. For most grid cells, the assigned depth represented an average depth over the cell. In order to represent flow restrictions in some cells, the minimum depth in the cell was more heavily considered in the averaging process. The assigned depths are presented in Table VI-5, which were directly output from WIFM. In interpreting Table VI-5, all water depths are in feet, preceded by a minus sign, and are with respect to local mean sea level (LMSL), which was taken 1 ft above MLLW. (Land elevations were assigned a value of +10.)

Incorporation of Hydrographic Survey Information

71. In order to properly model circulation within Mississippi Sound, the depth field must be accurately specified along transects across barrier island passes and bay entrances. Raytheon Ocean Systems was contracted by the Mobile District to obtain soundings at 50-ft intervals for the transects shown in Figure II-5. Shallow water areas and land obstructions were avoided and soundings were plotted in state (Louisiana, Mississippi, and Alabama) coordinate systems at a scale of 1:8000.

72. The method of incorporating the hydrographic survey data into the previously developed depth field is developed in the context of a journal as presented below.

Journal setup

73. Plots of transects were identified and labeled with respect to the general location map (Figure II-5). Requested transects, noted on small craft charts 11367, 72, 74, and 78, were contrasted to actual transects by checking beginning and ending points in state coordinates of transects on the plots and on the charts. In cases where differences did exist, actual transects were added to the charts. Latitude and longitude of end points of the surveys were then interpolated from the small craft charts.

74. A journal was prepared (Table VI-6) identifying assigned labels for the various transects, giving latitude/longitude and state coordinates of the end points of each transect, and identifying pertinent nautical charts.

Procedure for transferring grid lines to sounding plots

75. The various documents used and their scales are: (a) small craft charts - 1:40000; (b) nautical charts - 1:80000; (c) sounding plots - 1:8000; and (d) subgrids - 1:80000. All measurements were taken using a scale divided into sixtieths (1/60) of an inch.

76. The transects as actually surveyed were transferred to the nautical charts from the small craft charts using latitude/longitude in combination with common land feature identification, the 2:1 scale relationship serving as a control for accurate placement.

77. The nautical charts were overlaid with the corresponding subgrid to identify the affected cells. A 1:10 scale factor was used to transfer the grid lines to the sounding plots. Each cell was then identified and labeled by its grid coordinates. As each nautical chart contained several transects, it was possible to identify in terms of state coordinates at least one lateral grid line to serve as a control for consistent lateral line placement. Vertical line placement was controlled by visual comparison of the chart and sounding plot.

Comparison of Previously Assigned Depths to Surveyed Depth

78. The nautical chart with subgrid overlay and depth grid (Table VI-5) was used to refine cell identification with regard to model features to account for related cells and special cases.

79. The overlaid nautical charts had been used in assigning initial cell depths, thus their use in comparing survey depths with previously assigned depths would serve as a control so that the whole cell could be viewed in conjunction with the transect.

80. The depth grid (Table VI-5) was used to list individual cell depths along each transect. Then each sounding plot was examined to determine a representative depth range in each cell. The representative range was compared with the previously assigned depth together with the specific cell on the overlaid nautical chart to determine if a cell depth needed to be corrected. A table was prepared to show the results of these comparisons (Table VI-7).

Table VI-7 (Concluded)

(Sheet 3 of 3)

Barrier Island Configuration

81. All barrier islands were located on cell faces with a land elevation of 10 ft. The barriers were modeled as exposed barriers; no overtopping occurred at any barriers in any of the simulations. The barrier islands are given in Table VI-8. The orientation labeled 1 indicates a u-face barrier, while the orientation labeled 2 represents the barrier obstruction to be along the v-face of the cell as shown in Figure A-1.

Flow Inputs

82. The major flow inputs (see Table VI-9) and their locations in the grid will be considered. Average daily flow values as obtained from the United States Geological Survey (USGS) are employed in the numerical model.

Calibration/Verification Stations

83. In order to compare simulated water surface elevations with the observed values, the location of the water surface elevation stations must be located on the grid. Results are shown in Table VI-10.

84. The placements of the meteorological and velocity/salinity stations are given in Tables VI-11 and VI-12, respectively.

PART VII: SELECTION OF THE CALIBRATION AND VERIFICATION PERIODS

85. In order to understand the general behavior of the hydrodynamics and salinity distribution in Mississippi Sound over the sampling period, river inflows, meteorological station wind information, and salinity transect data were tabulated. A brief discussion of the significant findings and the tables themselves are presented in turn for each data group. Periods for numerical study are selected based upon these findings and on modeling requirements. The selection process is presented in detail in the final section.

River Inflows

86. United States Geological Survey (USGS) daily average streamflows were tabulated from April-September 1980 for the major streams to be considered in the numerical model as shown in Table VII-1. Flow for the Biloxi River System consisted of flows in the Tchoutacabouffa and Biloxi Rivers and Bayou Bernard. Total drainage areas for these three systems totaled 588.68 square miles (Bettandorff 1972). Daily mean flows for the Biloxi River at Wortham, Miss., (Station 02481000) were obtained from the USGS. The drainage area at Wortham, Miss., was given as 96.11 square miles. The total flow for the Biloxi River System was estimated by multiplying the Wortham, Miss., gage reading by 6.1251 = 588.68/96.11. The flow for the Jourdan and Wolf System was obtained similarly. The drainage areas totaled 759.20 square miles for the two rivers at Mississippi Sound (Bettandorff 1972). Daily mean flows at Station 02481510 on the Wolf River near Landon, Miss., (drainage area 308.28 square miles) were multiplied by 2.4627 = 759.20/308.28 to estimate the total inflow to the Sound.

87. The total drainage area of the Pascagoula River System as given by the USGS is 9498 square miles. Daily mean flows at Station 02479000 at Merrill, Miss., gage (drainage area 6590 square miles) were multiplied by 1.4413 = 9498/6590 to estimate the total inflow into Mississippi Sound. Based upon USGS Water Supply Paper No. 1763 (Harvey et al. 1965), this flow was divided between the West Pascagoula and Pascagoula Rivers as follows. The West Pascagoula River received 0.6 of the flow with the remaining 0.4 of the flow being assigned to the Pascagoula River.

(Sheet 5 of 5)

88. The development of the Mobile River System was treated as described by Schroeder (1979). The total inflow to Mobile Bay was assumed to be equal to 1.07 times the sum of the gage readings for the Tombigbee River at Coffeeville, Ala., Station 02429761 and the Alabama River at Clairborne, Ala., Station 02429500. To allow for the travel time, the resulting inflow time series was lagged by 5 days to estimate the inflow time series at Mobile Bay.

89. The total drainage area reported by the USGS for the Pearl River at its mouth is 8669 square miles. To estimate flow into Mississippi Sound, daily mean values at Station 02489500 near Bogalusa, La. (drainage area 6630 square miles) were multiplied by 1.3075 = 8669/6630.

90. River inflows were high in the spring months (April and May) and receded during June and were relatively low in July, August, and September. Total average daily inflows for all six river systems were 518,000 cfs, 258,000 cfs, 77,500 cfs, 39,150 cfs, 23,900 cfs, and 16,900 cfs for April, May, June, July, August, and September, respectively.

Meteorological Station Wind Data

91. Daily maximum hourly averaged wind speeds and daily maximum (2-sec gust) wind speeds were tabulated over the survey period at Station 4 on Horn Island as shown in Table VII-2. For periods in which data at Station 4 were not available, data were tabulated for Station 2 at Ship Island as shown in Table VII-3 to provide a record of wind information as complete as possible. The range of daily maximum hourly averaged wind speed was 5.6 (July 10) to 31.7 (April 13) mph. The range of daily maximum winds speed was 10.7 (July 10) to 45.4 (April 13) mph. Typical daily maximum hourly averaged windspeeds were 20, 12, 10, 15, 13, 8-28, and 8-24 mph for April, May, June, July, August, September, and October 1980. April and early May constituted a period of relatively high winds. Fall storms occurred in September and October. The gages were removed during Hurricane Allen (7 August-17 August).

Salinity Transect Data

92. Throughout the 180-day survey period at approximately 3-week intervals, salinity transects were obtained at locations shown in Figure II-4. Salinity values were measured at 5-ft-depth intervals. In order to characterize

Wind Characteristics for Meteorological Station 2, Ship Island

* Gage possibly malfunctioning.

the general horizontal salinity distribution, middepth salinity conditions for 11 stations are shown in Table VII-4 with the range over depths listed underneath the middepth value. Stations T26, T28, T30, T36, and T42 characterize the western portion of the Sound. Stations T2, T52, and T54 represent the central portion of the Sound, while stations T60, T70, and T80 portray conditions in the eastern section of the Sound. In referencing the table, if one goes across the table at any one date, the horizontal salinity distribution is obtained. If one goes down a column, the change in conditions over time are represented for each station, group, or for the entire Sound. In April and May 1980, the entire Sound, particularly the western end and the entrance to Mobile Bay, exhibited very low salinity. As June progressed, salinity levels increased overall. This trend continued through July. By August, conditions in the Sound had stabilized to a summer pattern. Note that the 8/22-23 transect values correspond very closely to the 9/24-25 values.

93. Horizontal salinity gradients are largest in the Spring. However, local gradients may be found throughout the period in the highly transient Lake Borgne (T26) and Mobile Bay (T80) entrances.

Calibration and Verification Periods

94. It is desirable to calibrate and verify the hydrodynamic parameters (bottom stress) and salinity parameters (dispersion coefficients) separately but over the same periods. The following criteria are used to select the calibration and verification periods:

- a. Streamflow must remain relatively constant. Storm or flood periods exhibiting time-varying flow characteristics are discarded from consideration.
- b. In order to minimize wind effects, periods for which wind speeds are minimum are to be considered.
- <u>c</u>. Since continuous salinity levels are available at only six stations (VS stations in Figure II-1), it will be necessary to employ salinity transect values in defining the initial conditions. Therefore, these periods must begin in a transect day.

95. By considering river inflows (Table VII-1), wind conditions (Tables VII-2 and VII-3), and salinity transect conditions in Table VII-4, a general understanding of the dynamics of the Sound may be obtained.

96. In the numerical study of the Sound, it is necessary (for reasons of computational cost) to consider a 5- to 6-day period. This constraint Table VII-4 Representative Spatial Salinity Transect Data, 1980 (ppt)

coupled with the previous three criteria is sufficient to determine the periods for numerical study.

97. Consider Table VII-4; the 4/28-4/29 period is eliminated due to excessive wind and highly transient flood flow conditions. The 5/21-5/22 period, although relatively calm, exhibits transient flow conditions and is discarded. The 7/23-24, 8/22-23, and 9/8-9 periods exhibit excessive wind and are eliminated. The 9/2-3 transect is incomplete and therefore this period is not considered.

98. The 6-day period, 9/20-9/25, was selected for further study as a potential calibration period for both hydrodynamics and salinity mechanisms. From the hydrodynamic perspective, the astronomic tide characteristics at Pascagoula as shown by Outlaw (1983, Plate 42) indicate that during 9/23 and 9/24 the semidiurnal constituents M_2 and S_2 assume increasing importance as the tidal range is reduced on entering a neap tide period. From the salinity perspective, values are relatively constant in time over this period. Therefore, salinity transect values obtained over the 2-day period, 20-21 September may be used to define initial conditions. In addition, the 24-25 September values may be used as values to compare with the numerical results. Maximum daily hourly averaged wind speeds are less than 9.0 mph over the entire period. Therefore, wind effects should be small.

99. The 5-day period, 6/12-6/16, was selected for further study as a potential verification period for both hydrodynamic and salinity mechanisms. From the hydrodynamic viewpoint, the astronomic tide characteristics at Pascagoula as shown in Outlaw (1983, Plate 39) indicate that the diurnal constituents 0_1 , K_1 , P_1 dominate and determine the character of the tide. The tide range is characteristic of a Spring tide. From the salinity viewpoint, this period exhibits a relatively large horizontal gradient. Vertical salinity gradients are significant in the middle and eastern station groups in Table VII-4. The maximum daily hourly averaged wind speed declines from 16.1 to 11.4 mph from 6/12-6/13 and to less than 8.0 mph for the 6/14-6/16 period. The vertical salinity gradients indicate that the middle and eastern sections of Mississippi Sound are partially mixed, while the western section is reasonably well mixed. The vertically integrated two-dimensional modeling concept employed for salinity may not be applicable during this period. As a result, salinity was not considered. The hydrodynamic mechanisms were verified using this Spring tide period.

PART VIII: CALIBRATION PERIOD 20-25 SEPTEMBER 1980

100. In order to obtain a more detailed understanding of the dynamics of the Sound prior to simulating this period, hourly values of wind speed and direction and salinity are considered in turn below. A complete set of salinity transect values are presented in order to investigate the degree of stratification. Based upon the results of the harmonic analysis, the predicted values of water surface elevation and currents are developed and compared versus the unfiltered (raw) data.

Wind Information

101. Hourly wind speeds and directions are as shown in Table VIII-1. At most stations average hourly wind speeds are below 10 mph, with daily maximum wind speeds (2-sec gust) below 20 mph. Wind direction and velocity are relatively uniform spatially at each hour over the period. The wind effects should be relatively small on water surface displacements over this period.

Instantaneous Salinity Information

102. Hourly values of salinity meters nearest middepth were considered. Middepth locations were selected as being the most appropriate to compare with the vertical averaged model results. The range for each day at each station as located in Figure II-1 is given in Table VIII-2. Salinity levels are normally within a range of approximately 1-2 parts per thousand for all days. The maximum spatial difference over the Sound is approximately 5-6 parts per thousand.

Salinity Transect Information

103. Representative middepth salinity values are shown in Figure VIII-1. The salinity range over depth is given to indicate the degree of stratification. Stratification effects even within the navigation channels were not significant during this period. Therefore, the well-mixed assumption appeared to be valid during this period.

104. In order to investigate the reliability of the instantaneous

salinity and temperature data obtained using the deployed conductivitytemperature sensors, the salinity and temperature transect values obtained using a field salinometer were compared at common times and spatial locations as shown in Table VIII-3.

105. In most instances, temperature values were extremely close. However, the salinity values obtained from the conductivity-temperature sensors tended to be 2-3 parts per thousand lower than the field salinometer values. Raytheon Ocean Systems Company (Parker 1981) indicated that there were biological fouling problems with the conductivity probe. Antifouling paints cannot be used on the sensor because the metal ions released by such paints affect the conductivity readings. Therefore, in analyzing the salinity data, the instantaneous salinity data should be considered less reliable then the salinity transect data. Since salinity transect data were available for 20-21 September and 24-25 September these data were used to establish initial conditions and as calibration data, respectively.

Water Surface Elevation Information

106. Program TIDE (Appendix B) was developed to predict the tidal elevations presented in Part III after Schureman (1940) based upon the constituent amplitudes and phases. Astronomic data are calculated in order to determine constituent node factors and equilibrium arguments at the start of the prediction period. Based upon specified amplitudes and local epochs for the O_1 , K_1 , P_1 , M_2 , and S_2 constituents, as given previously in Tables III-2 and III-3, the program reconstructs the water surface elevation for each station. Subroutine TAPE accesses the edited hourly elevations as provided by NOAA and the filtered elevations input to the harmonic analysis so that these elevations may be printed next to the reconstructed elevation at each hour of the prediction period.

107. Table VIII-4 presents the astronomic data with reference to Greenwich Mean Time (GMT). By employing local epochs, the time reference is transformed directly to Central Standard Time (CST). Consider the Pascagoula station, 874-1196; tidal constituents are given in Table VIII-5. Since local epochs are used, the water surface elevations given in Table VIII-6 are in CST beginning at 20 September, hour 00. Elevations are given for the first 2 days of the 5-day period. The unfiltered (UF) and filtered (F) columns present the

b,

unfiltered (edited NOAA) and filtered (harmonic analysis input) data, respectively. All elevations are with respect to NGVD (1929). Information analogous to that shown in Table VIII-6 for station 874-1196 is developed by the program for all other stations shown in Table II-3.

108. In interpreting the elevation table, it should be noted that predicted levels are based upon the five major tidal constituents $(O_1, K_1, P_1, M_2, and S_2)$, whereas the unfiltered levels contain all tidal energy. Reid and Whitaker (1981) note that these five tidal constituents contain approximately 95 percent of the tidal energy.

109. The unfiltered levels contain meteorological input in addition to all the tidal energy. In examining Table VIII-6, the filtered and reconstructed levels are usually very close (less than 0.1 ft). Unfiltered levels are 0.4-0.6 ft higher at each hour. The winds shown in Table VIII-1 do not appear to be of sufficient strength to account for all of the difference. In addition, this pattern in elevations holds at all other tidal stations as well. The majority of the 0.4- to 0.6-ft difference between unfiltered and reconstructed levels is believed to constitute a measure of the forerunner and far field surge of tropical storm Hermine, which passed through the Carribean over the Yucatan Peninsula and through the lower Gulf of Mexico during 20-25 September as shown in the 1980 supplement to Cry (1977). The magnitude of this effect as noted from the data is less than 0.6 ft, which is within the range of magnitudes of these effects observed for other tropical storms and hurricanes.

Current Component Information

110. Program TIDE may also be used to reconstruct tidal currents as well. Tidal currents are represented in E-W and N-S component form, with the E and N directions considered positive. The same astronomic data as given in Table VIII-4 are employed. The time reference is again CST since local epochs as shown in Table VIII-7 for station V10-S are used for each current component.

111. The unfiltered (edited), filtered (harmonic analysis input), and reconstructed currents for the first day of the 5-day period are given for station V10-S in Table VIII-8. Since a vertically integrated two-dimensional modeling approach is being employed, the meter nearest middepth was considered for stations shown in Table III-5, for which meters were placed at various

Table VIII-8 (Concluded)

depths. The subsets of stations considered are indicated by asterisks in Table III-5.

112. Predicted currents are reconstructed from the five major tidal constituents $(O_1, K_1, P_1, M_2, and S_2)$. The K_1 in Table III-7 contains both K_1 and P_1 energy. In order to separate K_1 and P_1 , at least 182 days of record are necessary. Since current meters were removed during the shrimp season and during Hurricane Allen, a complete 182-day record was not available for any of the current stations. As a result the K_1 constituent reported in Tables III-6 through III-9 contains P_1 energy and is valid only during the analysis period. Therefore, the total tidal current signal may be predicted at a given station only during the period given in Table III-5.

PART IX: VERIFICATION PERIOD 12-16 JUNE 1980

113. In order to obtain a more detailed understanding of the behavior of the Sound prior to simulating this period, hourly values of wind speed and direction and salinity are considered. A complete set of salinity transect values is also presented in order to investigate stratification effects Soundwide. Based upon the results of the harmonic analysis, the predicted values of water surface elevation and currents are developed and compared with the unfiltered (raw) data.

Wind Information

114. Hourly wind speeds and directions are as shown in Table IX-1. At most stations average hourly wind speeds are below 15 mph, while daily maximum wind speeds (2-sec gust) are below 20 mph. Wind direction and velocity are spatially uniform at any one hour over the period.

Instantaneous Salinity Information

115. Hourly values of salinity at meters nearest middepth appear to exhibit tidal variations at most stations. In order to investigate the temporal variations, the maximum and minimum values are given in Table IX-2, such that their difference (W) is maximum for the day given. Maximum daily variations in salinity range from 4.18 ppt at station 6S to 11.0 ppt at station 20M. The maximum spatial difference in salinity over the entire Sound is greater than 13 ppt as shown in Table IX-2. This period exhibits highly variable salinity conditions both in space and in time.

Salinity Transect Information

116. Representative middepth salinity values are shown in Figure IX-1. The range over depth is given to indicate the degree of stratification. Stratification effects are quite significant over the mid and eastern section of the Sound, even outside navigation channels during this period. The wellmixed assumption does not hold over these areas during this period. As a result, a two-dimensional vertically averaged approach may not hold for salinity.

12-16 June 1980 Continuous Station Salinity Levels

Table IX-2

 \bar{V}

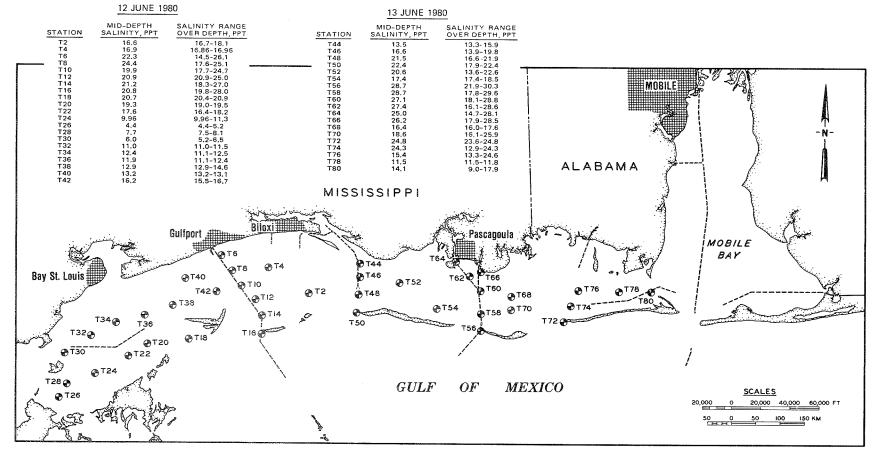

Figure IX-1. 12-13 June salinity transect data

117. It should also be mentioned that the biological fouling problem associated with the conductivity probe was also evident during this period. Instantaneous salinity values were consistently 2-3 ppt lower than corresponding salinity transect values. As a result, salinity transect values should be considered to be more reliable than the continuous salinity levels determined at the conductivity-temperature (CT) stations. However, the time and spatial variability characteristic of the continuous salinity data shown in Table IX-2 is considered valid. As a result, the initial salinity conditions cannot be specified using the transect data, since these data were obtained over 2 days and do not constitute a snapshot of the system. As a result salinity will not be simulated during this period.

Water Surface Elevation and CurrentComponent Information

118. The astronomic data, constituent node factor, and equilibrium arguments are shown in Table IX-3 for conditions at the start of the verification period. The major constituents at Pascagoula station 874-1196 are as previously given. The water levels are presented for this station in Table IX-4 from 20 September, hr 0, CST, for the first 2 days of the verification period.

119. In interpreting the elevation table, predicted levels are based on the five major constituents $(O_1, K_1, P_1, M_2, and S_2)$, whereas the filtered levels contain all tidal energy. The unfiltered levels contain meteorological input in addition to all the tidal energy. In examining Table IX-4, the filtered and predicted levels are usually within 0.1 ft. Unfiltered levels are within 0.3 ft of filtered levels. This difference is consistent with the wind information shown in Table IX-1. No tropical storms or hurricanes influenced Mississippi Sound during this period. Current data for station 10S were not available for this period; as a result station V10S was not considered.

Pascagoula 874-1196 Water Surface Elevation*

* Elevations with respect to NGVD (1929) in feet.

PART X: GLOBAL GRID HYDRODYNAMIC CALIBRATION AND VERIFICATION AND SYSTEM MODIFICATION

120. In this part, hydrodynamic simulation results over the global grid developed in Part VI are presented. Bottom friction mechanics (Manning's n versus stilled water depth) are calibrated considering the period 20-24 September 1980. The period 12-14 June 1980 was employed to verify the bottom friction. In order to consider the spatial extent of system induced changes in the hydrodynamics, a hypothetical system modification in the vicinity of Sand Island was made and a hydrodynamic simulation performed over the period 20-24 September. Salinity was not considered in any of these three simulations. As a result, meteorological effects (wind, surge setup, pressure anomaly) were not considered. The simulations corresponded to solely astronomic conditions.

Program TIDE (Appendix B) was incorporated in WIFM as a set of sub-121. routines in order to develop water surface elevations at the boundary of the global grid. Harmonic constants (mean amplitude and Greenwich epoch) developed by the GTM were input. Astronomic arguments, node factors, and equilibrium arguments are computed at the start of the simulation period. Contributions from each of the five constituents (O $_1$, K $_1$, P $_1$, M $_2$, and S $_2$) are summed to produce the predicted or reconstructed tidal elevation at the boundary. Since GTM grid spacing did not correspond to global grid spacings, it was necessary to employ an interpolation procedure. The amplitudes (cm) and phases (°Greenwich) are shown in Table X-1 for the 14 tidal signals located on the GTM grid as shown in Figure VI-1. The convective acceleration and eddy dispersion terms in the motion equations were set to zero on the solid and open boundaries of the global grid, thereby linearizing the motion equations at locations around the boundary. The same approach was employed around barriers. Subroutine ADVBAR (Appendix D) was developed in order to perform this task for the model user automatically. For global grid boundary cells (115, 22-59), values were interpolated linearly on cell-centered distances between the appropriate signals 1-5. For global grid boundary cells (31-114, 59) values were interpolated linearly on cell-centered distances between the appropriate signals 6-14.

122. Zero offset was assumed so that the reconstructed tidal signal oscillated about local mean sea level (LMSL), which was selected as the model datum. Based upon Table III-1, 1 ft was added to all soundings to convert their reference Gulf Coast Low Water Datum (MLLW) to the model datum (LMSL).

Table X-1 (Concluded)

(3 of 3 sheets)

123. All water surface elevations and velocity components were initialized to zero. A cubic polynomial feathering routine (Appendix C) was developed to smoothly transition the boundary elevations from zero to their reconstructed levels. The convective acceleration and eddy dispersion terms in the motion equations were set to zero on the solid and open boundaries of the global grid, thereby linearizing the motion equations at locations around the boundary. The same approach was employed around barriers. Subroutine ADVBAR (Appendix D) was developed in order to perform this task for the model user automatically.

124. During the calibration process, it was necessary to adjust the amplitudes of tidal constituents from the values tabulated in Table X-I. The GTM amplitudes were multiplied by the factors shown in the last column. Phases, as reported by the GTM, were used directly. In order to develop the appropriate amplitude multiplication factors, the harmonic analysis results obtained by Outlaw (1983) and those reported by Reid and Whitaker (1981) for the GTM were compared at the three deep sea pressure gages as shown in Table X-2. As can be observed, the Outlaw (1983) results were approximately 10-15 percent higher for the three major diurnal constituents. Pressure station 22 diurnal amplitude factors as reported in Table X-2 were used to modify the diurnal constituents of signals 8 and 9 in Table X-1. Pressure station 23 diurnal amplitude factors of Table X-2 were used to modify the diurnal constituents of signals 10 and 11 in Table X-1, while diurnal factors in Table X-2 for pressure station 24 were used to modify the diurnal constituents of signals 1-4, and 12-14 in Table X-1. Since simulation results employing the GTM results at the boundary are compared with the tide reconstructed from the O_1 , $\rm K_1$, $\rm P_1$, $\rm M_2$, and $\rm S_2$ constituents given by Outlaw (1983) in Tables III-2 and III-3, the use of the multiplication factors to make the GTM results consistent with Outlaw's (1983) results is warranted.

125. Initial attempts at employing this same procedure for the semidiurnal factors resulted in simulated tide exceeding reconstructed tides during the last 2 days of the 5-day (20-24 Sep 1980) calibration period, when the semidiurnal components were most important in determining the structure of the tide. In order to obtain the best fit between simulated and reconstructed tides during this period of the simulation, it was necessary to reduce the amplitudes of these constituents as shown in Table X-1 slightly below the levels reported by Reid and Whitaker (1981). The M_2 constituent was effectively reduced by 25 percent, while the S₂ component was essentially unchanged. In

Reid and Whitaker (1981) GTM Results

the immediate nearshore regions, the GTM results were used directly.

126. The depth versus Manning's n relationship shown in Table X-3 was calibrated. Simulation results employing the calibrated relationship are presented in Figures X-1 through X-11 for water surface elevations and in Figures X-12 through X-18 for u and v current components for 120 hr starting at 20 September hour 0000 CST. Results are presented from western to eastern Mississippi Sound. Simulated water surface elevations correspond more closely to predicted (reconstructed) values east of Gulfport. Although simulation results are acceptable in western Mississippi Sound, improvements could be made by including the effects of the Lake Pontchartrain system. The simulated depth averaged current components reveal the same structure; i.e., ebb and

flood pattern, as the predicted (reconstructed) middepth velocity stations. Since the K₁ and P₁ tidal current components could not be separated and the calibration period is outside the period for which K₁ and P₁ was determined for all stations (refer to Table III-5), the middepth velocity station predicted (reconstructed) data should be interpreted only in terms of general structure.

127. In order to verify the adjustments to the GTM constituent amplitudes and the calibrated depth versus Manning's n relation, a second period 12-14 Jun 1980 was considered. During this time, the structure of the tide was determined by the three major diurnal constituents. Since the character of the tide remained relatively constant, only 3 days were simulated. Initially all water surface elevations and current components were set to zero. After the first day, simulated levels corresponded quite favorably to predicted levels. Plots of simulated versus predicted (reconstructed) water surface elevations are shown in Figures X-19 through X-29 for the 72-hr period starting 12 June hour 0000 CST. The simulated depth averaged currents are compared with predicted (reconstructed) middepth values in Figures X-30 through X-36. Simulated water surface elevations correspond more closely to predicted (reconstructed) values east of Gulfport, as in the case of the calibration period.

Summary of calibration and verification

128. The calibration and verification periods comprise two different tidal regimes. During the calibration period, the character of the tide is changing from daily to semidaily and the range is less than 1.2 ft (neap tide). During this period the semidiurnal tidal components dominate. During the verification period, the character of the tide is relatively constant and is daily with a range greater than 1.9 ft (spring tide). During this period the diurnal tidal components dominate.

129. Since the simulated tidal levels correspond well to the predicted (reconstructed) results, the model may be confidently used to predict tidal elevations and currents over the complete tidal (lunar) cycle.

Hypothetical Sand Island Regional Dredge Material Disposal Site

130. Consider a hypothetical regional dredge material disposal site in the vicinity of Sand Island. The water depths with respect to local mean sea

level are modified as shown in Table X-4 in the vicinity of Sand Island to reflect accumulated dumping of dredged materials. The regional site encompasses an area of approximately 4.35 square miles. The modified depths over this area reflect a disposal of approximately 1.27 billion cubic feet (47.03 million cubic yards) of dredged material. To place this figure in perspective, over the 8-year period (1970-1979) an average of 13.7 million cubic yards per year were removed from Mississippi Sound (USACE, Mobile District 1979).

131. The 20-24 September 1980 period as employed in the hydrodynamic calibration was simulated assuming the hypothetical Sand Island regional disposal site was in place. Simulated water levels under this alternative at 11 stations were compared with the calibration simulation levels previously determined. Water levels within the Sound are unaltered by this hypothetical offshore disposal site even at grid cell (87, 27).

132. The detailed flow patterns in the vicinity of Sand Island are shown in Tables X-5 and X-6 for the present conditions at hr 72 and 120, respectively. The flow patterns in the vicinity of the hypothetical site are shown in Tables X-7 and X-8 at hr 72 and 120, respectively. Comparing Tables X-5 and X-6 and Tables X-7 and X-8, one notes that the detailed flow structure is changed only in the immediate vicinity of the hypothetical dredge material disposal site. Changes in flow structure induced by system modifications in Mississippi Sound and adjacent waters similar to the hypothetical Sand Island site will be felt only in the immediate vicinity and will not propagate to the boundary. Therefore, these modifications may be effectively studied using the global grid developed in this study.

SUPPLEMENTAL NOTES FOR TABLES X-5 THROUGH X-8

IN ORDER TO INTERPRET TABLES X-5 THROUGH X-8 CONSIDER THE GRID NOTATION IN THE FOLLOWING FIGURE.

THEREFORE IN TABLE X-5 FOR COMPUTATIONAL CELL (95, 6), THE Y VELOCITY COMPONENT IS -0.1 FPS, WHILE THE X VELOCITY COMPONENT IS -0.5 FPS.

OBSERVE IN TABLES X-7 AND X-8 THE HYPOTHETICAL DREDGE DISPOSAL SITE IS SKETCHED AS A SOLID LINE IN THE LOWER LEFT HAND CORNER.

NOTE: IN THE COMPUTATIONS ALL VELOCITIES NORMAL TO THIS LINE ARE ZERO.

PART XI: REFINED GRID METHODOLOGY AND APPLICATION

133. The global grid previously developed is to be used to provide boundary information for a set of refined grids. Each refined grid is to be located around a potential channel alteration project. Detailed circulation in the vicinity of the proposed channel modifications is to be studied within the refined grid. The assumption underlying this approach is that alternative channel alignments and/or deepening effects will be localized and will affect circulation only within the area covered on the refined grid.

134. The width of the principal navigation channels within Mississippi Sound is from 220 to 350 ft. It is desired to use space steps on the same order in the refined grid. Since the maximum depth even under proposed deepening alternatives is approximately 40 ft, the gravity wave speed in the refined grid area is less than 38 fps. Therefore, the explicit time step limit is less than 9 sec. We attempt to employ an implicit time step of 60 sec.

135. Consider a refined grid system such that when a given time period is simulated, the computational cost incurred will not exceed the amount required to simulate the same time period on the global grid. Observe on the 6785-cell global grid a time step of 360 sec was utilized. Thus to advance the simulation one time step on the global grid, six time steps will need to be performed on the refined grid.

136. The cost involved in inverting a matrix by the Thomas algorithm as employed in WIFM is approximately proportional to its rank cubed. Estimate the rank of the matrix to be inverted for a given grid setup as the square root of the number of cells in the grid, N, and obtain the following relationship assuming a unit proportionality factor:

$$W = (N)^{3/2}$$
 (XI.1)

where

W = cost involved in inverting the matrix for a given grid system
N = number of cells in the grid system

The total simulation cost, C , is then given by the following relation

$$C = MW \qquad (XI.2)$$

where

C = total simulation cost

M = number of time steps in the simulation

W = cost involved in inverting the grid system matrix

Let us equalize simulation cost in considering a given time period on each grid. In so doing, an upper bound on the number of grid cells to employ in the refined grid is obtained as follows

$$M^{g}W^{g} = M^{r}W^{r} = (6M^{g}) \left(\frac{N_{r}}{N_{g}}\right)^{3/2} W^{g}$$
 (XI.3)

Therefore if approximately 5000 cells in the global grid are involved in the computations: $6\left(\frac{N_r}{5000}\right)^{3/2} = 1$ and $N \approx 1500$. Thus a refined grid involving approximately 1500 cells in the computations must be constructed.

137. Let us now consider the general orientation of the principal navigation channels to the axes in the global grid as shown in Figure XI-1. As may be observed, the navigation channels do not run parallel, throughout their extent, to the global grid axis. If the refined grid orientation corresponds to that of the global grid, stair-stepping is normally employed to resolve the channel sections nonparallel to the grid systems. This approach, however, would necessitate the reduction of the space step by more than 100 percent.

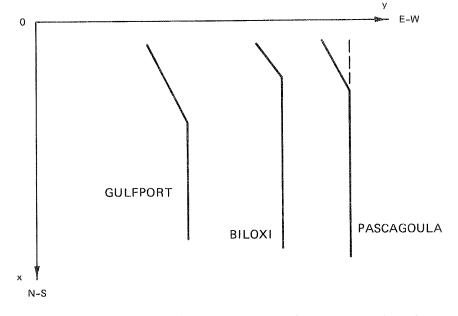

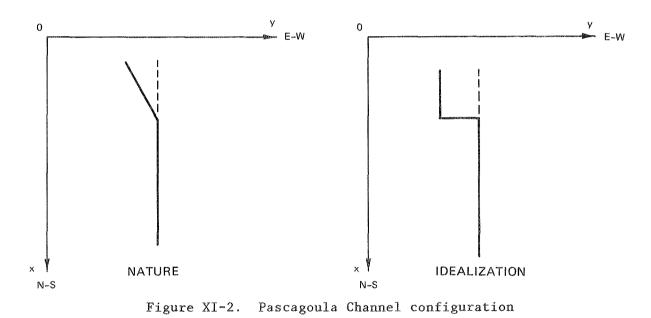

Figure XI-1. General orientation of major navigation channels in Mississippi Sound

As a result less than 750 cells could be used in the refined grid system to maintain a simulation cost for a given time equal to that of the global grid. This number of cells would probably be insufficient to resolve the channel properly in the refined grid. Therefore, it is necessary to idealize the channel systems somewhat within the refined grid. In order to demonstrate the refined grid approach on a typical navigation channel, the Pascagoula Channel was selected for further study. A refined grid was constructed in the idealized manner shown in Figure XI-2. By utilizing this channel idealization it was possible to employ the same orientation in the refined grid as in the global grid and use two dense vertical bands in the vicinity of the vertical channel sections and a single dense band of cells in the vicinity of the horizontal channel section. The details of the development of this refined grid system in the vicinity of the Pascagoula Channel are now presented. Pascagoula Channel refined grid

138. Nautical Chart 11374 at a scale of 1:40000 was used in mapping the refined grid.

139. The mapping for the horizontal (east-west) orientation is presented below in Table XI-1.

The grid obtained contains $49 \times 28 = 1372$ cells and is presented in Figure XI-3. In the above tables, the real space values are in map inches.

140. Program TGRID was employed to plot the refined grid at a scale of 1:40000 so that it would be overlaid on Chart 11374. The average depth over the cell was assigned as the cell depth in most cases. The hydrographic survey information was also used to modify channel depths and chart depths in the vicinity of the passes. The assigned depths are presented in Table XI-3, which was directly output from the model. All water depths are in feet preceded by a minus sign and are with respect to local mean sea level. All land is represented as +10 ft.

Barrier Island configuration

141. All barrier islands were located on cell faces and assigned an

Flow inputs and calibration stations

142. Two flow inputs for the Pascagoula River System are considered. The Pascagoula River is assigned as input to cell (8,1) and the East Pascagoula River is assigned as input to cell (16,1). Average daily USGS flows corrected by drainage area ratios were used to specify input flows in cfs.

143. The location of tidal stations, velocity stations, and salinity transect stations on the refined grid system are shown in Table XI-5.

Table XI-5 Calibration Station Locations on the Refined Grid

Global grid boundary interface

144. A subgrid of the global grid encompassing the Pascagoula Channel system was plotted at a scale of 1:40000. The global grid subgrid was overlaid the refined grid and boundary cells in the global grid surrounding the area were assigned to the nearest corresponding cell center of the refined grid. The assignments are shown in Table XI-6. During execution of the global grid simulation water surface elevations are written to logical unit number 25 and salinities to logical unit number 35. During execution of the refined grid simulation these two files are accessed, and linear in time and cell-centered linear in distance interpolations are performed to determine the refined grid water surface elevation and salinities at the boundary.

PART XII: REFINED GRID HYDRODYNAMIC CALIBRATION AND CHANNEL MODIFICATION

145. In this part, two hydrodynamic simulations over the Pascagoula Channel refined grid developed in Part XI are considered. Water surface elevations computed on the global grid for the 20-24 September 1980 calibration period were accessed to define the boundary conditions along the refined grid. The convective acceleration and eddy dispersion (advective terms) in the motion equation were not considered along the open and closed boundaries and around barriers (Appendix B) as well as in the two dense vertical bands used to describe the Pascagoula Channel and in the one dense horizontal band used to represent a section of the Pascagoula Channel. The sudden discontinuity in the depth profile outside the navigation channel was thought to perhaps cause problems in the advective calculations. For this reason, advection was not considered in the vicinity of the navigation channels.

146. In simulation one, the same Manning's n versus water depth relations considered in the global grid hydrodynamic calibration are used. The computed (Δ) versus predicted (reconstructed) water surface elevations are presented in Figures XII-1 through XII-4 for the 120-hr period starting 20 September hour 0000 CST. Simulated currents are shown in Figures XII-5 through XII-11. No predicted (reconstructed) currents are shown, since for this period, due to the K₁-P₁ separation problem, they cannot be determined. The simulated water surface elevations match very closely the predicted (reconstructed) levels. From this we may infer that the global grid boundary elevations are accurate and that the L-shaped representation of the Pascagoula Channel is sufficient to describe water surface elevations within the overall channel system.

Channel modification

147. In simulation two, the Pascagoula Channel was considered to be increased in width from 330 to 660 ft. The depth of the widened channel was maintained at 39 ft with respect to local mean sea level (model datum). The changes in depth required to update the original channel width are shown in Table XII-1. Hydrodynamics was considered over the same 5-day period used in simulation one. No wind effects were considered and salinity patterns were not simulated.

148. Simulated water levels for the channel modification are presented

versus predicted (reconstructed) levels for the unmodified system in Figures XII-12 through XII-15. Water surface elevations with the widened channel corresponded to the predicted (reconstructed) levels for the unmodified system and hence to the simulation one results.

149. The simulated current structure at hr 72 of the 5-day simulation period is presented in Table XII-2 for the 330-ft channel (simulation one) and in Table XII-3 for the 660-ft channel (simulation two). In considering Tables XII-2 and XII-3, the reader should consult the note on page 174. Observe the outline of the channel is indicated as a set of solid lines in both tables. The impact of widening the channel is felt locally in the vicinity of the channel (2-3 cells in width), and generally the changes are extremely small.

150. Based upon these results, the nested (refined grid) approach is appropriate for studying or identifying the extent of channel alterations on the local circulation pattern. To study circulation patterns within the channel area, a three-dimensional or two-dimensional laterally averaged model is needed.

PART XIII: SALINITY CALIBRATION ON THE GLOBAL AND REFINED GRID SYSTEMS

151. The simulation of salinity requires the consideration of meteorological as well as astronomical effects. Atmospheric pressure anomalies were not considered in this study. Predominate meteorological effects in most cases are due to wind. Therefore, the wind pattern must be studied for the period of consideration. The wind pattern is applied to develop a surface shear stress, which affects the hydrodynamic computations. Wind effects were not considered in the GTM simulations used to specify elevations along the boundary of the global grid. In performing combined global and refined grid simulations, the same wind pattern applied over the global grid is applied over the refined grid to develop the water surface shear stress effects over this grid. During the global grid simulation, water surface elevations and salinities are saved at various points within the global grid, which encompass the refined grid area. During the simulation on the refined grid, the previously saved water surface elevations and salinities are accessed to develop the appropriate boundary conditions.

Wind stress relations

152. The following form of wind stress is employed

$$\tau_{\rm w} = c_{\rm D} \rho_{\rm a} V_{\rm w}^2 \tag{XIII.1}$$

where

$$\begin{split} \tau_w &= \text{wind stress on the water surface} \\ C_D &= \text{dimensionless drag coefficient} \\ V_w &= \text{wind speed at the anemometer level} \\ \rho_a &= \text{air density} \end{split}$$

153. Several relationships are available for the determination of $C_{\rm D}$. Wilson (1962) employs $C_{\rm D}$ = 0.0015 for light wind conditions. Van Dorn (1953) employs $C_{\rm D}$ = 0.000923 for winds less than or equal to 14 knots.

154. Garret (1977) suggests the following power law relation

$$C_{\rm D} \times 10^3 = 0.51 V_{\rm w}^{0.46}$$
 (XIII.2)

where V is measured at the anemometer level in knots. (Note: 1 knot = 1.6884 fps = 0.5146 mps.) Evaluating XIII-2 at 14 knots, one obtains C $_{\rm D}$ = 0.00126 .

155. We observe the units of stress in Equation XIII-1 above are force per unit area (M/LT²). In the motion equations in the x and y directions, the units are in terms of acceleration (L/T²). Thus, in applying Equation XIII-1 to a motion equation, one divides the stress by the product of water density and depth; e.g., $(L/T^2) = (M/LT^2)/(M/L^2)$. Formally,

$$a_{w} = \frac{C_{D} \rho_{a} v_{w}^{2}}{\rho D} = \frac{K}{D} v_{w}^{2}$$
(XIII.3)

where

 $\begin{array}{l} \mathbf{a}_{\mathbf{W}} &= \operatorname{acceleration} \text{ induced by wind stress} \\ \mathbf{D} &= \operatorname{water} \operatorname{depth} \\ \boldsymbol{\rho}_{\mathbf{a}} &= \operatorname{air} \operatorname{density} \\ \boldsymbol{\rho} &= \operatorname{water} \operatorname{density} \\ \mathbf{V}_{\mathbf{W}} &= \operatorname{wind} \operatorname{speed} \operatorname{at} \operatorname{the} \operatorname{anemometer} \operatorname{level} \\ \mathbf{K} &= \operatorname{dimensionless} \operatorname{coefficient} \end{array}$

If we use $C_{\rm D} = 0.001$, we obtain $K = 1.191 \times 10^{-6}$. If we employ British units (slug, ft, sec), and $V_{\rm W}$ is given in mph , we multiply K by $(1.4667)^2$ to obtain 2.562×10^{-6} . This is the coefficient employed in the computer code.

Dispersion coefficients

156. The effective dispersion coefficients are assumed to have the form given in Equation V.64. The dispersion offsets due to wind are assumed equal to zero.

Global Grid Salinity Simulations

12-16 June 1980

157. This period was originally considered as a verification of the salinity computations. Initial conditions in Mississippi Sound were developed on the global grid based on salinity transect data. In order to verify the effective dispersion coefficients, model results were to be compared with continuous salinity data at the end of the 5-day period. Upon further study of the continuous salinity data and comparison with the salinity transect data

at common time and spatial location, it appeared that the continuous data were always lower than the transect data. Raytheon Ocean Systems acknowledged a biological fouling problem with the conductivity-temperature probe. Continuous salinity values always increased drastically after the meters were serviced. As a result of these data uncertainties, it was decided not to consider this period in the salinity study.

20-24 September 1980

158. This period was selected for calibration of the dispersion coefficients in the salinity algorithm. Salinity transect values were available on 20 and 21 September. These values were located on the global grid and two rectangular areas were set up in which salinity values were visually interpolated from the located transect values. National Marine Fisheries (1981) data were obtained for cruises #106 (April 1980) and #112 (November 1980) of the OREGON II. These data provided a general understanding of salinity patterns in the vicinity of the Mississippi Delta. A deep sea vertically averaged value of 36 parts per thousand was employed.

159. Initial conditions were assigned in a three-step process as shown in Table XIII-1. In step one, values were assigned based on cell water depth. In step two, salinity values were specified within Mississippi Sound based on salinity transect data. In step three, initial salinity values within Lake Borgne were specified in a zone format. In this process each succeeding step overrides the previous step.

160. Salinity boundary conditions which remained constant over time are shown in Table XIII-2. A cell-centered spatial interpolation analogous to that employed for water surface elevations was used to determine salinity values along the seaward boundary.

161. Meteorological effects were treated in the following manner. The surge setup due to tropical storm Hermine was approximately in the range 0.1-0.5 ft. The effect causes an increase or shift in the nodal datum corresponding to local mean sea level equal to the setup, which is less than 0.5 ft. Since soundings are not known to this accuracy in most areas of the Sound, the surge setup effect is negligible and was not considered. However, if one attempts to compare simulated water levels with the unfiltered (raw) elevation data, then the datum of simulated levels must be adjusted by this surge setup. Wind data over the period are presented in Table XIII-3. Based upon a study of the spatial and temporal wind variations shown in Table XIII-3,

Note: MET 2 was nonfunctioning this period. MET 3 and MET 1 are "land" stations. MET 4 and MET 5 are "island" stations. Speed (mph). Direction (magnetic).

GMT = CST + 6 hr.

* For Julian Day 269, GMT hr 6; average speed/direction = 9.4/158.

wind speed and direction were spatially averaged at 6-hr intervals.

162. A time step of 360 sec was employed 1200 times in order to simulate a 120-hr period starting at hour 0000 CST, 20 September. In order to remove the effects of transients in the hydrodynamics from the salinity computations, salinity computations were initiated after 240 time steps (1 day prototype time). Thus salinity computations were performed over the period 21-24 September. The initial conditions specified over the western portion of the Sound corresponded to the transect data taken on 20 September. Since salinity time variations in salinity were extremely small during this period, it was assumed that conditions on 21 September were effectively equal to conditions on 20 September. Simulation results at the end of the simulation (hour 2400 CST 24 September) were compared with transect data obtained over the western half of the Sound during the day of 24 September and over the eastern half of the Sound during the day of 25 September. Since time variations in salinity were extremely small, this was felt to be a valid procedure. Wind information input at 6-hr intervals was interpolated in time at each time step. Both salinity schemes were considered using the effective dispersion coefficient parameters shown in Table XIII-4. Note that C $_{\rm x}$ and C $_{\rm v}$ are in the interval of experimentally determined values (5.93, 20.2) as developed in Part V. The reduction factor, F = 0.0388, employed equals the ratio of the lateral to longitudinal dispersion coefficient as determined by Elder (1959) as reported in Part V. Therefore, the values of the calibrated dispersion coefficients are within the range of or are equal to experimentally determined values. The scheme 1 FCT results and the scheme 2 three-time level results are compared with measured data as shown in Table XIII-5. In most regions of the Sound, the scheme 1 and scheme 2 results are nearly identical and are in agreement with measured salinity values. However, in the vicinity of the Upper Mobile Bay freshwater inflow the results diverge as shown in Table XIII-6. The scheme 1 results are nonnegative and exhibit no oscillations. The scheme 2 results exhibit oscillations behind the freshwater front. Thus in order to study sharp front problems, scheme 1 is recommended.

Refined Grid Salinity Simulation

163. The 20-24 September period was simulated on the Pascagoula Channel refined grid using the Scheme 1 FCT approach. Boundary salinity and elevations

.

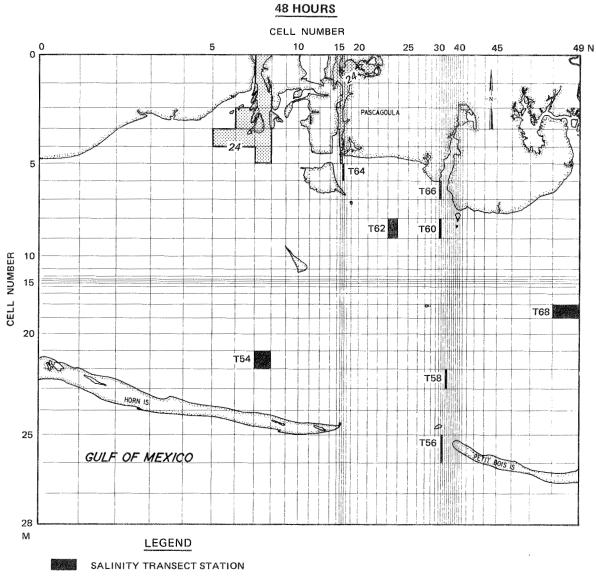

,

were accessed from the scheme 1 FCT global grid simulation for this period at the locations shown in Table XI-6. Temporal and spatial interpolation were employed to develop the boundary information at intermediate cells along the refined grid boundary. Initial conditions over the refined grid were determined from transect data collected on 20 and 21 September and were specified on a cell by cell basis. Since salinity variations in time were extremely small, it was assumed that the initial conditions were representative of conditions at hour 2400 CST on 20 September. In order to study the behavior of a purely freshwater inflow, zero values of salinity were specified for cells (8,1) and (16,1) representing the West Pascagoula and Pascagoula River inflows. Flows during the period were taken from Table VII-1 and were approximately 1600 and 1000 cfs for the West Pascagoula and Pascagoula. The surge setup generated by tropical storm Hermine was not considered.

164. A 60-sec time step was employed 7200 times in order to simulate the 120-hr period beginning hour 0000 CST 20 September. In order to allow hydrodynamic transients associated with initial conditions to dissipate, the salinity computations were initiated at time step 1440 (hour 2400 CST 20 September). Wind information employed for the global grid simulation at 6-hr intervals was interpolated in time at each time step. The calibrated effective dispersion coefficient parameters in Table XIII-4 were used to determine dispersion.

165. The growth of the freshwater influence is represented by computing the 24-ppt contour after 48, 72, 96, and 120 hr shown in Figures XIII-1 through XIII-4. Initial salinity values were larger than 24 ppt. Therefore, freshwater must dilute the water in any given cell to obtain a cell concentration less than or equal to 24 ppt. Salinity values in the shaded areas in Figures XIII-1 through XIII-4 are less than 24 ppt. Tidal conditions at 48, 72, 96, and 120 hr correspond to a mean level between high and low tides as shown in Figure XIII-5, which represents the water surface elevation at Pascagoula obtained during the global grid simulation. At 72, 96, and 120 hr, the tide is a lower high tide in a semidiurnal (neap) period.

166. Figures XIII-1 through XIII-5 indicate that the growth of the freshwater influence is a complicated function of wind loading (wind magnitude and direction history), freshwater flow rate, and tidal condition. It appears that salinity conditions are beginning to stabilize at the end of this 5-day period. However, the tidal range is relatively low corresponding to a neap

à.

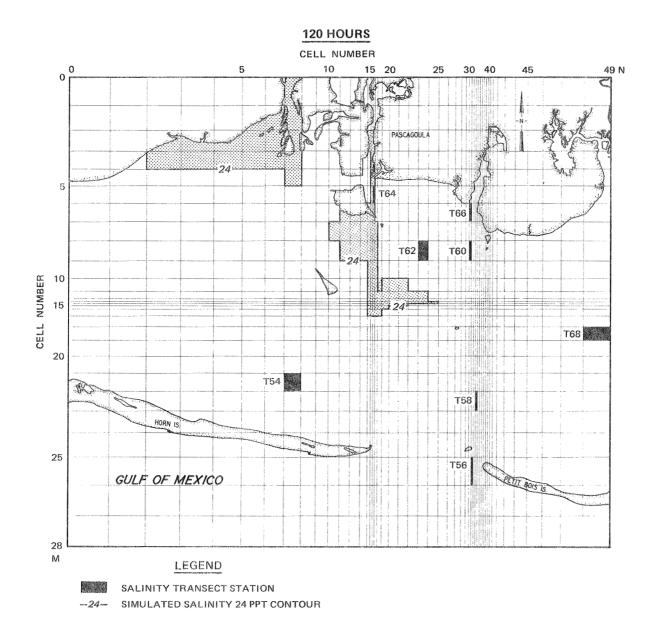

Figure XIII-4. Refined grid, 24-ppt salinity contour, 120 hr

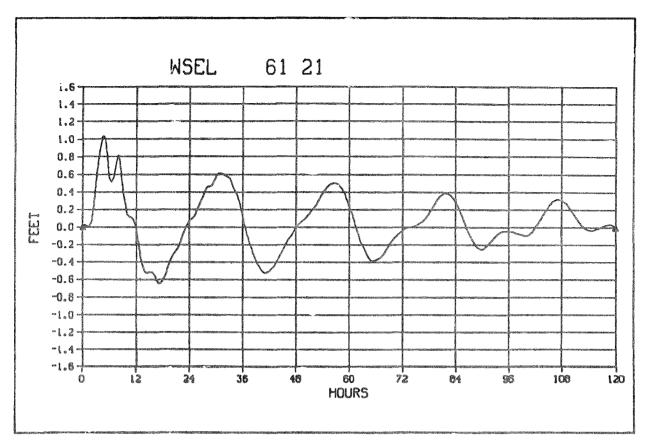

Figure XIII-5. Simulated global grid water surface elevation at Pascagoula including wind effect

tide and the Pascagoula River system inflows correspond to a late summer low flow condition. For higher tidal ranges and inflows it may require a significantly longer period in order to stabilize the salinity distribution.

167. Simulated velocity levels at 120 hr (24 September hour 24 CST) are compared with transect values measured on 24 and 25 September in Table XIII-7 at locations indicated in the darkened cells in Figures XIII-1 through XIII-4. As may be noted from these figures, the freshwater influence does not reach any of the transect stations. Therefore, the specification of inflow salinity values does not influence the simulation results at these locations. Simulated salinity levels at the transect station location correspond closely to observed values and further verify the dispersion coefficient parameters employed.

168. In order to study the behavior of refined grid simulation results in the neighborhood of the Pascagoula Channel inflow on a cell by cell basis, the initial salinity levels are compared with simulated levels at 120 hours (24 September hour 24 CST) in Table XIII-8. The simulated results appear to

Vicinity of the Pascagoula River Inflow

exhibit spurious fluctuations in cells (15-17, 2-6). This area of cells is located within the Pascagoula River itself as shown in Figure XIII-4. Although simulated salinity values are nonnegative, the behavior of the simulation indicates that the refined grid cannot be used effectively to predict salinity levels within the Pascagoula River itself. The numerical difficulties are due to the averaging process employed in coupling a two time level salinity finite difference scheme with a three time level hydrodynamic scheme. In practice, these difficulties would be resolved by employing an even more refined grid in the vicinity of the Pascagoula Channel inflow. 169. Salient study results are presented and the following conclusions are drawn.

Twenty-two tide gages, three deep sea pressure gages, and а. twenty-one oceanographic moorings arrayed with current meters at various depths were deployed over Mississippi Sound and adjacent waters over the period April-November 1980. Outlaw (1983) performed a harmonic analysis on filtered elevations and currents and determined tidal characteristics for nine constituents $(0_1, K_1, P_1, M_1, J_1, Q_1, M_2, S_2, and N_2)$. Since the GTM used to drive the global grid produced tidal characteristics for the five major tidal constituents $(0_1, ..., 0_n)$ K_1 , P_1 , M_2 , and S_2), tidal elevations at 11 stations and currents at 7 stations throughout the study area were reconstructed using Outlaw's (1983) results using these five major constituents for the calibration period 24-25 September and verification period 12-14 June 1980. Simulated water levels over the global grid matched reconstructed levels to within 0.2 ft at stations west of Pascagoula and to within 0.1 ft at Pascagoula and the stations to the east for both periods. Simulated current components exhibited the same general trend (flow reversal times) as the reconstructed currents at meters nearest middepth.

Based upon these results, the prototype data collection program and subsequent harmonic analysis provided sufficient water surface elevation and current data to calibrate and verify the bottom friction mechanics in the global grid hydrodynamics.

b. The simulated water surface elevations on the global grid for the calibration period 20-25 September were used to provide boundary elevations for a refined grid simulation for the same period. Simulated water surface elevations agreed with the reconstructed levels to within 0.1 ft at four data stations

within the refined grid. An L-shaped idealization was employed to represent the branching of the Pascagoula Channel.

Based upon these results, the idealization of the channel represented the actual system in sufficient detail to effectively simulate reconstructed levels on the refined grid.

- <u>c</u>. In the hydrodynamic simulation outlined in <u>a</u> and <u>b</u>, astronomic tide conditions were considered. Meteorological effects, namely, pressure anomaly, and long-wave setup must be con-sidered if one attempts to compare simulated hydrodynamic water levels and currents with the observed (unfiltered) data. For the calibration period, the long wave setup due to tropical storm Hermine is estimated to be approximately 0.3 ft.
- <u>d</u>. It was necessary to increase the amplitude of the diurnal $\begin{pmatrix} 0 \\ 1 \end{pmatrix}$, K_1 , P_1) and decrease the amplitudes of the semidiurnal $\begin{pmatrix} M_2 \\ 2 \end{pmatrix}$, S_2) tidal constituents from the values produced by the GTM in order to achieve hydrodynamic calibration and verification on the global grid and hydrodynamic calibration on the refined grid.
- <u>e</u>. Since M₂ and S₂ were dominant during the calibration period and O₁, K₁, and P₁ were dominant during the verification period, effectively all five constituents were considered during the calibration and verification process. Therefore, the hydrodynamics for any period may be effectively simulated on the global grid and refined grid.
- <u>f</u>. A hypothetical regional dredge disposal site in the vicinity of Sand Island studied on the global grid appeared to alter the tidal pattern only in lower Mobile Bay. Since the tidal pattern was not changed near the boundary, the boundary conditions supplied by the GTM remain valid and regional disposal alterations of this nature may be effectively studied on the global grid.
- <u>g</u>. The hydrodynamic effects of doubling the present channel width of the Pascagoula Channel as studied on the refined grid are localized to a narrow band of cells outlining the channel and

do not propagate to the boundary. As a result, adjustments to the navigation channels (minor adjustments in alignment, deepening, and widening) will induce changes in the flow pattern only in a narrow band of cells surrounding the area in which the adjustments are made. Flow changes will not propagate to the boundary, and the integrity of the global grid supplied boundary conditions will be maintained. This finding indicates that proposed changes in navigation channels may be studied on a case by case basis by developing individual refined grids around the appropriate channels. Boundary conditions for each of these refined grids may be developed using the global grid developed in this study.

i. Salinity data were collected at 40 stations encompassing Mississippi Sound over a 2-day period at regular intervals over the period April-November 1980. Conductivity-temperature readings were recorded and converted to salinity on a continuous basis at six locations over the entire Sound during the same period. Due to biological fouling of the conductivity-temperature probes, continuous salinity data could not be considered reliable and were not used to calibrate the salinity component of the model.

As a result, no observed time-varying salinity data were available. Transect data on 20-21 September and 24-25 September were used to establish initial conditions and provide conditions to compare with simulated salinities. Both the FCT scheme 1 and full three-time local explicit scheme 2 were considered on the global grid. Meteorological effect due to wind only was considered. Within Mississippi Sound simulation results for both schemes were nearly identical and corresponded to observed levels to within 1 ppt. In upper Mobile Bay, within the freshwater influence, scheme 2 results oscillated behind the freshwater front. The scheme 1 FCT results were nonnegative and nonoscillatory. Although due to the nonavailability of time varying salinity data, the global grid salinity calibration is not as rigorous as the hydrodynamic, the

calibrated dispersion coefficient parameters are within experimentally determined ranges.

j. The simulated water surface elevations and salinity levels on the global grid for the calibration period 20-24 September were used to provide boundary conditions for a refined grid simulation for the same period. Temporal and spatial distributions of freshwater fronts associated with the Pascagoula River system were studied using the FCT scheme 1 approach. Meteorological effect due to wind only was considered. During the 21-24 September period, the freshwater front associated with the Pascagoula River inflow (1000 cfs) extended along the channel and into the middle of the Sound. In contrast, the freshwater front associated with the West Pascagoula River inflow (1600 cfs) was confined to an area near the shoreline. This front appeared to be driven to the west by the prevailing winds which were from the south-southeast. Simulated salinity levels corresponded to within 2.3 ppt of measured transect values at all eight stations, which all were located outside the region of freshwater influence.

As a result of the closeness of the comparison, the calibrated values of effective dispersion coefficient parameters were substantiated further.

<u>k</u>. The growth of the freshwater fronts associated with the Pascagoula and West Pascagoula Rivers was influenced by the wind magnitude and direction, the magnitude of the freshwater inflows, and the astronomic tide.

As a result, in considering alternatives to the Pascagoula Channel, care must be taken in developing representative conditions for these phenomena.

- 170. The following recommendations are made based upon study results.
 - <u>a</u>. In the development of additional refined grids for study of alternate channel systems, an implicit time step in the neighborhood of 60 sec can be economically employed with a minimum

space step on the order of the channel width and a grid with 1000-1500 computational cells.

- b. In studying the effects on salinity of dredge practices on either the global or refined grid, the FCT scheme 1 is preferred over scheme 2 for sharp front problems. However, scheme 1 is on the order of three times slower than scheme 2. Thus, if fronts are not sharp; i.e., if one specifies the same value of salinity for the flow input as is found in the neighboring cells of the inflow, scheme 2 may be effectively employed.
- <u>c</u>. Additional research is warranted to flux correct the three time level explicit scheme (scheme 2). This research would produce a reasonably fast (approximately 50 percent faster than the present scheme 1) but accurate transport scheme and eliminate the averaging of the hydrodynamic variables used in scheme 1 FCT.
- d. Due to the dependence of the salinity distribution associated with freshwater fronts on wind, flow rate, and astronomical tide, it is recommended that additional simulations be performed in order to develop the sensitivity of the salinity distribution with respect to each of these influences. The results of this sensitivity analysis would provide useful information in developing design scenarios for each channel alteration project.

APPENDIX A: GUIDE TO WIFM MODEL INPUT REQUIREMENTS

1. The preparation of the necessary input data required by WIFM is considered in light of the need to develop additional refined grids in the vicinity of navigation channels (Gulfport and Biloxi). This appendix is not intended to be a complete user guide but to outline in detail the requirements necessary in developing an input data deck for a refined grid system. The basic requirements are presented in Table A1. Each item in this table is discussed in terms of WIFM-SAL input requirements using the Pascagoula Channel refined grid system developed in this study. A complete description of model input variables and required data formats is reported by Schmalz (1984).

Table A1

WIFM Input Requirements for a Refined Grid

- I. Plot global subgrid encompassing the refined grid region
- II. Map the refined grid system
- III. Specify the depth field
- IV. Specify the barrier characteristics
- V. Specify flow input locations and discharges
- VI. Specify tidal signal input
- VII. Specify initial salinity conditions
- VIII. Specify wind information
 - IX. Specify simulation control variables

Mapping the Global Subgrid of Pascagoula Region

2. Initial development of the refined grid required reproducing the complete global grid of Mississippi Sound.

3. Program MAPIT was executed using the table of input variables previously prepared in generating the global grid. Once this file was stored a subgrid of the region selected (in this case, Pascagoula Channel) was plotted at the same scale (1:40000) as that chosen for the refined grid. The global subgrid was overlaid on the project map (chart 11374) for the refined grid in order to facilitate commonality of feature specification.

Mapping of Pascagoula Channel

4. The first effort to map a grid of approximately one thousand (1000) cells having three (3) bands of high resolution was unacceptable.

5. The aspect ratio (cell width versus length) exceeded desirable limits. Aspect ratios should be less than 20.

6. To reduce the aspect ratio and total number of cells required, the second effort eliminated two of the high resolution bands. This grid, while only 1034 cells (47 \times 22), once plotted and overlaid chart 11374 was clearly inadequate (with only one high resolution band) to model the branching channel into Pascagoula.

7. The third effort attempted increasing the number of cells, decreasing the region to be mapped and adding a fourth band of high resolution. This produced a grid of 2058 cells (49 \times 42). While the grid would allow better idealization of the channels and rivers it was considered too large for economical computation.

8. Using this third grid as a guide, the following decisions were made with regard to producing the final grid:

- <u>a</u>. Left boundary of refined grid coincided with global grid, N = 53 .
- <u>b</u>. Bottom or seaward boundary of the refined grid coincided with global grid M = 33.
- <u>c</u>. Three high resolution bands whose cells, 0.1 map inches in width (300 ft in nature), were positioned to achieve an idealized channel. Two dense bands were mapped in the y direction, at the main channel and at the west river, and one band was mapped in the x direction at the channel junction.
- <u>d</u>. The right boundary of the refined grid extended to approximately global grid N = 67.
- <u>e</u>. The upper (land) boundary extended to approximately global grid M = 18.

9. The final grid covered an area from near Bellafontaine Point to near Point Aux Chenes Bay. Tables A2 and A3 show the Y , Y', and α and X , X', and α for the Y direction and the X direction, respectively. These input variables for Program MAPIT produced a grid of 1372 points (49 × 28). The scale is 1:40000 and the file is ordered as follows: Y direction

A2

Y	Υ'	
<u>Map in.</u>	<u>Map in.</u>	<u>α</u>
1.0	2.10	1
8.0	1.56	4
10.5	1.00	2
12.25	0.75	2
14.1	0.50	2
15.1	0.50	2
15.6	0.10	2
15.8	0.10	2
16.5	0.45	3
18.9	0.50	5
20.0	0.25	3
20.5	0.10	3

22.1	0.40	3
27.2	1.40	6

Table A2 Y Direction Mapping*

* The Y direction was mapped from west to east (left to right), thus the WIFM numbering convention was followed.

Table A3

X Direction Mapping*

X	X'	
<u>Map in.</u>	<u>Map in.</u>	<u>α</u>
1.0	1.5	1
4.0	1.5	2
11.1	0.75	7
12.3	0.5	2
12.8	0.1	2
13.0	0.1	2
13.5	0.5	2
15.0	1.0	2
19.5	0.8	5
24.0	1.5	4

* The X direction was mapped south to north (bottom to top). The WIFM numbering convention was not observed, thus the file is ordered in the opposite direction, i.e. refined grid cell M = 2 is global cell number M = 27. followed by X direction. The refined grid was then plotted on paper and mylar by using the DOGRID procedure.

10. The stretching coefficients were also punched using the DOGRID procedure for subsequent input to WIFM-SAL.

Depth Field Specification

11. The depth field was digitized from nautical chart 11374 (Ed 16) dated November 1980. All cells designated as the idealized channel were set to depth -38 (project channel depth). Cells representing land were set to depth +10. The datum was MLLW, Gulf Coast Datum.

12. The bathymetric surveys (Raytheon Ocean Systems Co. June/July 1980) for Horn Island Pass (Transect 11A, B, C) was reviewed to ensure that depths assigned to the band of high resolution cells in the pass would reflect the survey. The depth field comprises Card Group 13.

Barrier Specification

13. Barriers were specified for the refined grid based upon the island configuration and shallow depth areas. For barrier specification all the barriers were assumed to be exposed throughout simulation and barrier elevations were set to +10 ft.

14. Barriers are located on either the u or v face of each cell. Figure A-1 shows this orientation.

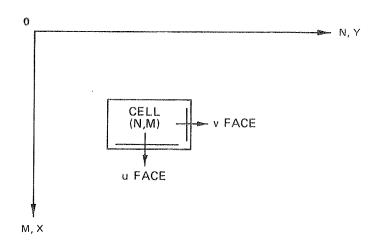

Figure A1. Barrier cell face orientation

15. To code the barrier location, IDIR is set to 1 for a u face barrier and set to 2 for a v face barrier. IDIR indicates flow direction.

16. Further to locate the barrier it has to be specified by its refined grid indices and their range. The following examples illustrate:

A barrier on the u cell faces of cells (4, 24) (5, 24) and (6, 24) is coded thus:

ITYP	INDX	IDIR	I1	12	13
			М	Na	N _b
1	1	1	24	4	6

Il is the M row of the u face barrier location. I2 and I3 correspond to the range of columns (N's) that the barrier extends along row M (I1).

17. Alternately, a barrier on the v cell faces of cell (7, 2) and (7, 3) is coded:

ITYP	INDX	IDIR	I1	12	13
			Ν	Ma	М _ь
1	1	2	7	2	3

Il is the N column of the u face barrier and I2 and I3 correspond to the range of rows that the barrier extends along column N (I1). Barrier location codes are the first set of input variables in Card Group 17.

Flow Specification

18. Freshwater inflow locations were noted for the Pascagoula and West Pascagoula Rivers in terms of the refined grid coordinate system.

19. Location information is specified in the boundary input Card Group 17. For the West Pascagoula the input is specified as follows.

			Refined Grid Indices						
ITYP	INDX	IDIR	М	N ₁	^N 2				
9	1	1	1	8	8				

ITYP = 9 for a flow input. IDIR = 1 for a vertical oriented x axis oriented inflow. INDX specifies the discharge array. Since this inflow is the first inflow specified, INDX = 1.

20. Note in simulating salinity, salinity values associated with the given inflow must also be specified in Card Group 21.

Tidal Signal Input Specification

21. To specify the locations for the tidal signal inputs, where the global and refined grid interface, the cell centers of the global grid cells on the refined grid boundaries must be referenced in their respective refined grid indices. To accomplish this, all cells in the global grid where tidal inputs would be made to the refined grid were identified and numbered. Forty (40) global grid cells lie along refined grid (water) boundaries. To identify their centers in optimum refined grid indices, the refined grid was overlaid the global grid. Table A4 lists the tidal signal inputs and their N, M indices in both the global and refined grid. The refined grid M indices are the IGX array; the N indices are the IGY array (Card Group 3a).

22. The forty cells in the table are assigned boundary values based upon the results obtained at their corresponding locations in the global grid. For intermediate refined grid points interpolation is required. To specify interpolation along the x-axis for cells (1, 6) through (1, 8) in the refined grid the following data are required.

			I1	12	I3	I4	15	16
			Ref	Eined	Grid	Boundary Sweep	Tide	Inputs
ITYP	INDX	IDIR	N	M_{1}	M ₂	Orientation	Signal _A	Signal _B
8	1	2	1	6	8	0	1	2

Note I4 = 0 for a lower sweep boundary and IDIR = 2 for x interpolation ITYP = 8 for a tidal elevation boundary. Observe in Table A4 that signals 1 and 2 correspond to cells (1, 6) and (1, 8) in the refined grid. Thus values at refined cell (1, 7) will be interpolated from the values of tidal signal inputs 1 and 2 (based upon x distance).

23. To specify interpolation along the y-axis for cells (5,28) through (8,28) in the refined grid the following data are required.

			I1	12	13	14	15	16
			Ref	ined	Grid	Boundary Sweep	Tide]	Inputs
ITYP	INDX	IDIR	М	$^{N}1$	N ₂	Orientation	Signal _A	$\operatorname{Signal}_{\mathrm{B}}$
8	1	1	28	5	8	1	29	30

		Tabl	le A4			
Global	Grid	Cell-Refined	Grid	Cell	Boundary	Assignment

A7

Note I4 = 1 for an upper sweep boundary and IDIR = 1 for y interpolation. ITYP = 8 for a tidal boundary. Observe in Table A4 that signals 29 and 30 correspond to cells (5, 28) and (8, 28) in the refined grid. Thus values at refined cells (6, 28) and (7, 28) will be interpolated from the values of tidal signals 1 and 2 (based upon y distance).

Salinity Initial Condition Specification

24. The calibration period (20-24 September 1980) was selected for simulating salinity on the refined grid.

25. Initial conditions for each cell were specified by transferring the calibration period initial salinity values from the global subgrid to the refined grid. To facilitate this task, the global subgrid (scale 1:80000) was reproduced and the initial salinity values were recorded thereon. Then the refined grid was reproduced at scale 1:80000 and overlaid on the subgrid.

26. Initial salinity conditions for the global subgrid had been specified based upon salinity transect surveys taken during 20-21 September 1980.

- 27. See Table A5 for transect station location summary.
- 28. Salinity initialization is specified in Card Group 13b.

Specification of Wind Information

29. The user has the option of considering wind effects on the hydrodynamics and the salinity. Wind speeds are input in miles per hour and wind directions are in the meteorological or "from" convention as opposed to the oceanographic or "to" convention (0° from the N, 90° from the E, etc). Wind speeds and directions may be entered in tabular form in Card Group 11.

Development of Simulation Control Variables

30. Simulation control variables determined by the grid and depth characteristics are DX , DY , and TAU , which are specified in Card group 4.

31. DX is the vertical spatial stepsize, while DY is the horizontal spatial stepsize. These variables are determined from the scale at which the grid was mapped. In this case the mapping was at the 1:40000 scale, where 1 in. equals 40,000 in.

A8

32. DX is the real space prototype distance (ft) represented by one unit (in.) in the grid in the vertical or M direction. Thus

$$DX = \frac{4000 \text{ in.}}{12 \text{ in./ft}}$$
 or 3333.33 ft

33. DY is the corresponding value associated with the Y or N direction of the grid. In the refined grid the same scale was used for mapping both directions. DX equals DY.

34. TAU is the time-step length and was determined in the following manner.

$$\Delta t = \frac{\Delta S \min (ft)}{\sqrt{g(ft/sec^2) * d_{max}(ft)}}$$

where ΔS is the minimum of DX times the smallest X expansion coefficient (Mu) and DY times the smallest Y expansion coefficient (Nu).

[Mu is the smallest X expansion coefficient; i.e., the smallest X prime chosen for the mapping = 0.10].

[Nu is the smallest y expansion coefficient; i.e., the smallest y prime chosen for the mapping = 0.10].

g is the acceleration of gravity = 32.2 ft/sec.

d is the maximum depth of water assigned to a cell in the depth field = 50 ft.

 Δt is the explicit time step limit.

Thus

$$\Delta t = \frac{3333.33 \text{ ft*0.1}}{\sqrt{32.2 \text{ ft/sec}^2 \times 50 \text{ ft}}} = 8.3 \text{ sec}$$

This is the maximum time step that can be used for explicit modeling. Since WIFM-SAL is an implicit model, TAU can be up to 10 times larger than Δt . TAU for the refined grid was set to 60 sec.

35. Surface elevation, velocity, and salinity stations within the region represented by the refined grid were plotted onto nautical chart 11374 (Ed 16). This put all the prototype data station location and the depth information for the model in one place. Station locations were then plotted onto the refined grid and global subgrid. Table A5 summarizes the locations and their N, M indices in both grids.

36. This table forms the basis for assignments to the control variables in Card Groups 25, 26, and 27 which are the plotting controls.

NNPOT - number of surface elevation stations
NVELPN - number of velocity stations
INPOT - N indices of surface elevation stations
IMPOT - M indices of surfaces elevation stations
NVCORD - N indices of velocity stations
MVCORD - M indices of velocity stations
37. The value of NFREQ (input Card Group 5) can be determined here.

NFREQ = $\frac{3600 \text{ sec/hr}}{\text{Tau sec}}$ or $\frac{3600}{60 \text{ sec}} = 60/\text{hr}$. Thus hydrodynamic data will be printed every 60 time steps or once per hour at each of the data stations.

38. The N, M indices of the hydrodynamic gages form the two arrays NPOT and MPOT which are WIFM-SAL input Card Group 8. The total number of hydrodynamic prototype gages is the value of NGAGE (input Card Group 5).

Table A5 Data Station Location Summary

1. Station V16 $_{\rm B}$ located beyond right of cell 49,22 outside the refined grid.

- 2. Station T7 located beyond right of cell 49.5 outside the refined grid.

Station T56 located at cell boundary between 33,26 and 34,26.
 Station T60 located at cell boundary between 32,16 and 33,16.

APPENDIX B: PROGRAM TIDE

1. Program TIDE is a general purpose program to predict the tidal characteristics (elevation or current component) given the harmonic constants and prediction period. The program also will access water surface elevation and current component tapes containing the results of the standard harmonic analysis (filtered and unfiltered values). Based upon the harmonic constants for the analyzed stations, the program predicts the station tidal characteristics and outputs the value next to the unfiltered and filtered values at each hour. This serves as a check on the harmonic analysis. The program also will write to a WIFM compatible plot file the predicted tidal characteristic at user specified locations. During the WIFM simulation, this plot file is accessed to enable overplotting of predicted tidal characteristics on computed results at common locations, thereby aiding the hydrodynamic calibration process.

2. The input variables are defined followed by a listing of the program. Program TIDE:

IYEAR - Year of the prediction (e.g. 1980) IMONTH - Month of the prediction (e.g. 9) Start Time of the Prediction Period - Day of the prediction (e.g. 20) TDAY - Hour of the prediction (e.g. 00) IHR ICONST - 37 element array, specify 1 in the appropriate array element if the constituent in NCONST array is to be considered in developing node factors and equilibrium arguments. NTIDE - Number of tide stations $\begin{pmatrix} 1 - \text{elevation} \\ 2 - \text{currents} \end{pmatrix}$ NCOMP - Number of tidal components NT - Tape logical unit number NCON - Number of tidal constituents to include in the predictions ICONST(J), J = 1, NCON - Number of the array element in NCONSTcorresponding to each tidal constituent considered. 1 Access harmonic analysis data tape IEL - Data Tape Access Switch 0 Don't access harmonic analysis data tape NUL - Lower hour of prediction period to write to WIFM plot file NUH - Upper hour of prediction period to write to WIFM plot file IWR - Number of stations to write to WIFM plot file NWR (I), I = 1, IWR - Number of the station to write to WIFM plot file based on the input sequence of all stations

NTT - Logical unit number of WIFM plot file Subroutine TAPE: Harmonic Analysis Data Tape Format TITL(J, I1, I), J = 1, 8 - Title on the harmonic analysis data tape of the current station information file Note: (I1 = 1, NST), where NST is the number of stations (I = 1, NR), where NR = 2* NCOMP (filtered and unfiltered files) JDAY - Start Julian Day IHR - Start Hour IMIN - Start Minute DELT - Data Interval (Minutes)

APPENDIX C: CUBIC POLYNOMIAL FEATHERING

1. In employing tidal constituent signals along the grid boundary, there is no guarantee that at simulation start time these signals will be zero. In fact, in general this will not be the case. Since water surface elevations and currents are set to zero at the start of the simulation, there is a discontinuity or impulse at the boundary; e.g., the boundary level is not consistent with the initial condition. This phenomenon may lead to oscillations in the numerical solution, which may persist over several computational cycles.

2. In order to avoid this problem, the true tidal signal, g(t), is replaced by a more well-behaved signal, f(t), at model start and for a number of initial time steps of length Δt . The well-behaved signal is zero at simulation start time and at some time T_1 , > 0, the well-behaved signal and one or more derivatives equal the true signal and its corresponding derivatives. Consider the following cubic polynomial, $f(T) = aT^3 + bT^2 + cT + d$,

$$f(o) = o \rightarrow d = o$$

$$f(T_1) = aT_1^3 + bT_1^2 + cT_1$$
 (C.1)

$$f'(T_1) = 3aT_1^2 + 2bT_1 + c$$
 (C.2)

$$f''(T_1) = 6aT_1 + 2b$$
 (C.3)

From Equations C.1 through C.3, we obtain a , b , and c :

$$a = \left[f(T_1) - T_1 f(T_1) + \frac{T_1^2}{2} f''(T_1) / T_1^3 \right]$$
(C.4)

$$b = (f''(T_1) - 6aT_1)/2$$
(C.5)

$$c = f'(T_1) - 3aT_1^2 - 2bT_1$$
 (C.6)

Thus, we have determined a cubic polynomial with value zero at t = 0, and whose functional plus first two derivative values equal those of the true

boundary signal. Required information for determining a , b , and c are $f(T_1)$, $f'(t_1)$, and $f''(T_1)$.

3. Consider the true boundary signal to be a periodic signal as shown in Figure C1 below.

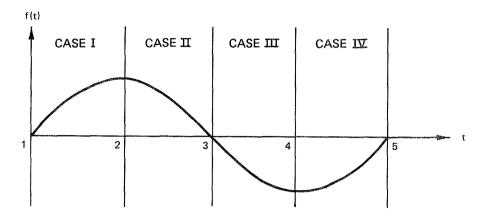

Figure C1. Periodic boundary signal

4. Since the start time may be arbitrary, the vertical axis may fall anywhere between 1 and 5 and four cases must be considered as shown in Figure C-2. A level x > 0 is specified (XLEVEL), this enables $f(T_1)$ to be determined in each case. The following approximations are employed for $f'(T_1)$ and $f''(T_1)$.

$$f'(T_1) = \frac{g(T_1 + \Delta t) - g(T_1 - \Delta t)}{2\Delta t}$$
(C.7)

$$f''(T_1) = \frac{g(T_1 + \Delta t) + g(T_1 - \Delta t) - 2g(T_1)}{(\Delta t)^2}$$
(C.8)

Note $f(T_1) = g(T_1)$.

5. The flow inputs were also feathered in the following fashion. The user specifies the number of time steps (NTID) over which the feathering is to take place. The feathered signal equals zero at the start of the simulation. At each intermediate time step less than NTID, the feathered signal is obtained by linearly interpolating between its zero value at time zero and the true boundary value at time step NTID.

6. The feathering procedures are contained in Subroutine POLY, which is listed in Table B1. This subroutine is called if the user specifies IFETR = 1 on input.

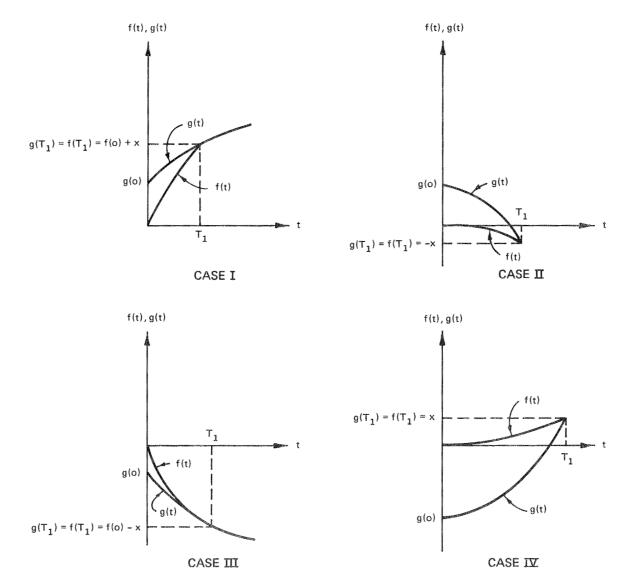

Figure C2. Cubic polynomial feathering conditions

APPENDIX D: SUBROUTINE ADVBAR

1. WIFM-SAL employs a cell face flag convention to control the hydrodynamic computations in each sweep of the computational grid. The cell flag codes are stored in two arrays: ICU for the x sweep u-face control and ICV for the y-sweep v-face control. The ICU array consists of a two-digit pair, U_1U_2 , while the ICV array contains the two-digit V_1V_2 pair for each cell in the grid. For an open-cell face the first digit U_1 or V_1 is a six. The second digit U_2 or V_2 controls the advection approximation employed in evaluating the convective acceleration and eddy-dispersion terms in the motion equations as tabulated below:

- 0 no advection
- 1 x-direction only
- 2 y-direction only
- 3 both x- and y-directions
- 4 normal in y-direction, approximation in x-direction
- 5 normal in x-direction, approximation in y-direction
- 6 approximation in x-direction only
- 7 approximation in y-direction only
- 8 approximation in both x- and y-directions

At the grid boundaries, solid boundaries, and cell-face barriers, no advection has been performed in the computations for both the global and refined grids. Therefore no approximations to these terms have been made (linearized motion equation has been considered) and codes 4-8 have not been used in this study. Subroutine ADVBAR, as shown in Table D-1, determines the appropriate codes for U_2 and $V_2 \equiv (0, 1, 2, 3)$ for linearizing the appropriate motion equations around cell-face barriers. Prior to the development of this routine, the model user was required to specify these codes through input for cells surrounding cell-face barriers. In the Mississippi Sound global grid 111 bariers (Table VI-8) are employed, while on the refined grid 25 barriers are employed. The work required in developing the codes by the user would have been indeed substantial in this application and has been eliminated through the use of Subroutine ADVBAR.
