1 BACKGROUND

This report includes a description of the regional and local geology of Palm Beach County, a sediment characterization of the native beach and a preliminary sand source evaluation. Native beach characteristics are summarized in **Tables 1 and 2**. The proposed offshore sand source and existing core borings are depicted on **Plates 1 and 2**. Potential upland sand sources are depicted on **Plate 3**. Boring logs and available laboratory results are attached in the Appendix. Additional borings may be needed within the sand source during the design phase of this project.

1.1 REGIONAL GEOLOGY

The Florida Peninsula occupies a portion of the much larger geologic unit called the Florida Plateau. Deep water in the Gulf of Mexico is separated from deep water of the Atlantic Ocean by this partially submerged platform nearly 500 miles long and 450 miles wide. In the last 200 million years, the plateau has been alternately dry land or covered by shallow seas. During that time up to 20,000 feet of carbonate and marine sediments were deposited. There has been a tilting of the Florida Plateau about its longitudinal axis. The west coast is partially submerged, as indicated by the wide estuaries and offshore channels, while the east coast is correspondingly elevated, showing the characteristics of an emergent coastline.

During the last million years, a series of four glacial periods, or ice ages, brought about significant changes in sea level. As a result of these sea level fluctuations, the Florida peninsula was again covered and uncovered by shallow seas. Following the first glacial period, sea level rose 270 ft. above its present level. Dry land on the Florida peninsula was then restricted to a few small islands along the central Florida ridge and in northeast Florida.

About 100,000 years ago, the last glacial period began. Sea level fell to 300 feet below its present level and the Florida Plateau emerged as dry land. Approximately 15,000 years ago, sea level began its most recent rise towards present sea level (Shinn, 1988). Sea level rose at an average rate of 30 feet per 1,000 years. About 7,000 years ago, the rate of sea level rise slowed when the sea level was about 30 feet below its present level. It was at this most recent slowing of sea level rise that the modern barrier islands of southeast peninsular Florida formed.

1.2 LOCAL GEOLOGY

Four inlets link the Intracoastal Waterway with the Atlantic Ocean along Palm Beach County's 45 miles of open-ocean shoreline. Jupiter Inlet, at the northern end of the county, was a natural waterway, connecting the Loxahatchee River with the ocean. Originally, the inlet was

kept open naturally but flow was reduced after the construction of the Intracoastal Waterway and Lake Worth Inlet. Since 1947, the inlet has remained open with regular dredging.

The Jupiter Carlin Segment of the Palm Beach County Shore Protection Project is located in northern Palm Beach County, on the barrier island beach, immediately south of Jupiter Inlet in the Atlantic Coastal Ridge physiographic region. The Savannah, Altamaha, and other rivers of Georgia and the Carolinas have transported sand to the Florida east coast; shore currents and wave action gradually shifted this sand southward. The combined effect of wind and wave action has formed much of this sand into successive parallel ridges or dunes. Unconsolidated sand and shell underlain by a limestone/sandstone base compose the Florida beaches.

The foundation for most of the barrier islands in Palm Beach County is the Anastasia Formation. This rock formation appears at several places in the county as a submerged reef that generally parallels the shoreline. The exposed formation appears at various locations from the high water line to approximately 1,000 feet (ft) offshore. Nearshore rock outcroppings exist in the project area. The most prominent outcropping occurs near Florida Department of Environmental Protection (FDEP) range monument R-18. A portion of this outcropping extends above mean high water, and the remainder extends into the nearshore area.

2 NATIVE BEACH

2.1 GENERAL

The following native beach information was taken from "Geologic Investigation of Potential Borrow Areas, Offshore Singer Island Site, Palm Beach County, Florida," prepared by RWParkinson Consulting, Inc. for Taylor Engineering, Inc. on August 9, 2012 and updated October 12, 2012.

2.2 NATIVE BEACH SAMPLING AND ANALYSIS

In February 2009 Taylor Engineering collected beach samples to characterize existing conditions from FDEP reference monuments R-13 to R-15 in Palm Beach County (Table 1). This area has been subjected to numerous beach fill projects using sand derived from offshore sources and periodic maintenance dredging of the ICWW and Jupiter Inlet sand trap. As such, the sedimentology of these samples reflects the presence of fill in addition to what has accumulated naturally on the beach.

Table 1: Beach Characteristics (2009)

Monument	Location	Mean (mm)	Mean (phi)	% Carbonates	% Fines (230)	Sorting	Munsell Color
R-13	Dune	0.5	1.01	63.2	0.09	0.94	5Y 5/1
	Berm	0.6	0.73	64.9	0.27	1.32	5Y 5/2
	MHW	0.35	1.51	40.5	0.06	0.59	5Y 5/2
R-14	Dune	0.38	1.38	47.9	0.28	1.18	5Y 5/1
	Berm	0.31	1.69	44.2	0.09	0.74	5Y 4/1
	MHW	0.31	1.69	41.9	0.11	0.76	5Y 4/1
R-15	Dune	0.38	1.38	24.1	0.28	1.18	10YR 6/1
	Berm	0.39	1.36	42.6	0.08	0.59	5Y 5/1
	MHW	0.29	1.79	30.8	0.05	0.67	5Y 4/1
AVERAGE		0.39	1.39	44.46	0.15	0.89	5Y 4/1 to 5Y 5/1

Taylor (2009) noted the "truest measure of native beach sand" was that reported by CPE and ERM in 1994 (Table 2) because those samples were collected before the 1995 nourishment project. Both data sets indicated that the beach consisted of fine-grained sand. The CPE and ERM sediment is more poorly sorted, which likely reflects the inclusion of coarse-grained shell fragments; a common occurrence in the nearshore, sub-tidal zone. Taylor did not collect samples below the intertidal zone.

Table 2: Composite Beach Characteristics (1994)

Monument	Sample Elevation	Mean (mm)	Mean (phi)	% Carbonates	% Fines (230)	Sorting	Munsell Color
R-13, R-17	+6.5'	0.34	1.55	ND	0.97	1.49	ND
	+2.5'						
	-1.5'						
	-5.5'						
	-9.5'						

3 SAND SOURCES

3.1 PROPOSED OFFSHORE SAND SOURCE

One sand source, "Jupiter/Carlin A," was identified by the project sponsor as the preferred source of material for the Project. The sand source lies in water depths of approximately 60 to 70 feet, centered about two miles offshore, between the Palm Beach county line, south to FDEP range monument R-10. Irregular in shape, the sand source encompasses approximately 700 acres. The vicinity map, shown on **Plate B-1**, illustrates the location of the sand source**. Plate B-2** shows the location of previously collected vibracores.

Palm Beach County collected 29 vibracores within the proposed sand source in 1995 and 1996 and performed grain size analyses on selected samples. Boring logs and laboratory testing results are attached in the **Appendix**. Palm Beach County collected 20 additional vibracores in 2016. As of the writing of this document, the laboratory results had not been finalized. Based on the 1995 and 1996 data, the thickness of potential beach-compatible material ranges from 4 to 20 feet, with an average thickness of more than 10 feet. Conservative dredge cut depths and a 15-year-old bathymetric survey were used to estimate an available volume of approximately 5 million cubic yards. This should allow for plenty of material in the sand source for the Project beach fill, which is anticipated to be approximately 800,000 cubic yards. The sand source does contain rock and large shell that will require screening. Vibracores were typically collected at a spacing greater than 1,000 feet, which is the minimum distance required for permitted sand sources. As such, it is expected that additional core borings will be collected and laboratory analyses performed to ensure that the material is compatible with the beach placement area and is in compliance with FDEP's "Sand Rule" guidelines.

3.2 UPLAND SAND SOURCES

For purposes of plan formulation, only offshore dredge costs were considered. However, upland sand mines have been used by the sponsor in the past and, due to budgeting, scheduling and future material availability, sand mines may need to be used again.

Five commercial sand venders have been identified for truck haul nourishments (**Plate B-3**). Sand vendors were identified based on their proximity to Palm Beach County, their ability to meet the sand quality criteria and their ability to meet the anticipated quantity and production requirements for the project. Sand from all five mines is natural, not manufactured, and each will require processing to meet the project's sand specification. All five mines have an available volume of sand that far exceeds the required volume for the project. **Table 3** summarizes the characteristics of the potential upland sand sources.

Table 3: Characteristics of Upland Sand Mines

Sand Mine	Mean Grain Size (mm)	Sorting (Phi)	% Fines Passing #230	% Retained on #4	Munsell Color Value
Stewart – Fort Pierce[1]	0.46	1.19	1.17	0.0	6
Stewart – Immokalee[1,2]	0.35, 0.57	0.90, 1.01	0.46, 0.88	0.0	8, 7
Vulcan – Witherspoon[2]	0.59	0.61	0.22	0.0	8
Jahna – Ortona[2]	0.46	0.82	0.10	0.0	7
A.C.I. – Homestead[3]	0.45	1.11	1.57[4]	0.0	7

1. Geotechnical data obtained from the report "Feasibility Evaluation of Upland Truck Haul as a Beach Fill Construction Method in Broward County, FL – Segment II" prepared by Olsen Associates, Inc and Coastal Planning and Engineering, Inc, June 2012.
2. Stewart Immokalee values shown represent products identified as "Beach Sand" and "Beach Sand #2," respectively.
3. Geotechnical data provided by Atlantic Civil, Inc.
4. Percent Fines for the ACI mine are based on material passing the #200 sieve.

3.2.1 Stewart Mining Industries – Fort Pierce

The Stewart Fort Pierce mine is located in northern St. Lucie County. The mine produces two types of sand: silica and silica with carbonates, mostly in the form of broken shells. The material produced is mined by a dragline excavator. The dragline bucket dumps the material into piles and a front end loader transports the material to a processing plant. The processing plant first removes larger material using vibrating screens with spray bars. The sand is then fed into dewatering screws that remove the remaining fines. The resulting sand is placed onto a conveyor and stacked in piles, from which it is loaded into trucks. The Fort Pierce mine has been the primary source of upland sand for the Jupiter Carlin Segment of the Palm Beach County Shore Protection Project.

3.2.2 Stewart Mining Industries – Immokalee

The Stewart Immokalee mine is located just northwest of the City of Immokalee in northwestern Collier County. The Immokalee sand is extracted from the lake pit by hydraulic dredge and pumped through pipes to a sand processing plant. The processing plant first removes larger material using vibrating screens with spray bars. The remaining smaller grains are separated into 11 different gradations using water and gravity. The sand is then remixed depending on the client's specifications and fed into dewatering screws. The dewatering screws remove remaining fines due to their weir-like effect. The resulting sand is placed onto a conveyor and stacked in a sand pile.

3.2.3 Vulcan Materials – Witherspoon

The Vulcan Witherspoon mine is located in southern Glades County, near the city of LaBelle, approximately 120 miles from the project area. The Witherspoon mine claims to have the deepest dredge in the western hemisphere. The sand is extracted from the lake pit by hydraulic dredge and pumped to a sand processing plant. The processing plant first removes larger material using vibrating screens. The remaining grains are separated using water and gravity. The sand is then mixed, based on the desired specifications, and fed into dewatering screws to remove the fine-grained material. The resulting material is then stockpiled on site.

3.2.4 E.R. Jahna – Ortona

The E.R. Jahna Ortona mine is also located in southern Glades County, adjacent to the Witherspoon mine and approximately 120 miles from the project area. Sand from the Ortona mine has been used extensively for beach fill projects throughout southeast Florida. Sand is extracted from the mine pit using one of two cutter-head dredges and pumped to a central processing plant. The processing plant first removes larger material using vibrating screens with spray bars. The remaining material is sent through a gravity classifier and remixed to match the desired specifications, then fed into dewatering screws to remove the remaining fine-grained material. The resulting material is then stockpiled on site.

3.2.5 Atlantic Civil, Inc. – Homestead

The ACI mine is located in southern Miami-Dade County, in the city of Homestead and approximately 35 miles from the project area. The ACI mine has not been used previously to produce fill material for beach nourishment. Sand will be extracted using either a dragline or gantry dredge. The material will be screened to remove the oversized material using a mobile vibrating screen. The sand will then be transported to the central wash facility where it will be screened and washed through sand classifying screws and cyclone(s). The material will then be stockpiled on-site.

4 COMPATIBILITY OF THE SAND SOURCES WITH THE BEACHES

Florida Administrative Code 62B-41.007(2) (the Florida Sand Rule) requires that beach fill maintains the general character and functionality of the material occurring on the beach and in the adjacent dune and coastal system. Such material shall be predominately of carbonate, quartz or similar material with a particle size distribution ranging between 0.062 mm and 4.76 mm, shall be similar in color and grain size distribution to the material in the existing coastal system at the disposal site and shall not contain:

- Greater than 5 percent, by weight, silt, clay or colloids passing the #230 sieve
- Greater than 5 percent, by weight, fine gravel retained on the #4 sieve
- Coarse gravel, cobbles or material retained on the 3/4 inch sieve in a percentage or size greater than found on the native beach
- Construction debris, toxic material or other foreign matter
- And shall not result in cementation of the beach

4.1 OVERFILL AND RENOURISHMENT FACTOR

The Overfill and Renourishment Factors were calculated to estimate the predicted performance of the sand sources with respect to the native beach materials, both during initial beach stabilization and over the long term. Thus, they help in choosing the best available material. The factors also are used to calculate fill construction volume and renourishment volumes. Overfill and Renourishment Factors are calculated using the sediment mean grain size and standard deviation of the native beach and the sand source in phi units.

The Overfill Factor (R_a) is primarily a volume factor which may be used to calculate an intentional overfill to compensate for volume loss during the initial construction. The R_a is used to determine which of the proposed sand sources will provide the lowest placement volume, and thus is most compatible with the existing beach. The Ra for all potential sand sources was calculated using the USACE Coastal Engineering Manual (CEM) software program.

The Renourishment Factor (R_J) estimates long term relative erosion rates of sand source materials with respect to native materials. This is done by assuming all grains have a finite residence time in the local littoral system before being transported offshore or alongshore. Larger grains remain longer. The R_J is primarily a measure of relative long-term stability. R_J values greater than one predict the sand source will erode at a higher rate than the native beach. Conversely, values of less than one predict the sand source is more stable than the native beach. Sand source compatibility is summarized in **Table 4**.

Table 4: Sand Source Compatibility

Parameter	Offshore	Upland					Native Beach (1994)
	Jupiter/ Carlin A	Ft. Pierce	Immokalee[1]	Witherspoon	Ortona	ACI	
Mean (mm)	0.59	0.46	0.35, 0.57	0.59	0.46	0.45	0.34
Sorting (phi)	1.27	1.19	0.90, 1.01	0.61	0.82	1.11	1.49
Munsell Value	ND	6	8, 7	8	7	7	ND
Overfill Ratio (Ra)	1.0	1.0	1.65, 1.0	1.03	1.0	1.0	NA
Renourishment Ratio (Rj)	0.67	0.89	1.33, 0.68	0.80	0.68	0.59	NA

1. Stewart Immokalee values shown represent products identified as “Beach Sand” and “Beach Sand #2,” respectively.

4.2 OFFSHORE SAND SOURCE

Based on the sediment classifications shown on the logs, laboratory testing was performed on most of the core borings. However, limited statistical analyses were available for only six of the 29 vibracores within the proposed offshore sand source, Jupiter/Carlin A. A review of the available geotechnical data for the proposed sand source suggests that the material is compatible with the beach placement area. The mean grain size of the surficial sand from the six analyzed vibracores was 0.59 mm with a standard deviation of 1.27. The mean grain size is expected to be reduced after in-situ rock is screened out during the dredging process. **Table 4** shows a comparison of the 1994 native beach data with the available sand source data. Additionally, the sand source sediment color was described typically as gray to dark gray and tan to brown. Based on these descriptions the sand source color appears to be compatible with Taylor’s (2009) beach characterization of gray to dark gray sand. A more comprehensive geotechnical investigation will be required to perform a full compatibility analysis.

4.3 UPLAND SAND SOURCES

Five upland sand mines were identified as potential sand sources. The material from all five mines is natural but requires processing to remove the course-grained and fine-grained material in order to meet the sand specification. As a result of the sand processing, material from all mines is very similar. The main difference between the mines is that the Immokalee, Witherspoon, and Ortona mines are almost 100% quartz and the Homestead and Fort Pierce

mines are a mix of carbonate and quartz material, based on available laboratory data. **Table 4** is a comparison of characteristics of the native beach and the potential upland sand sources.
